MIDDLE AGES. The designation applied to the historical period between the times of classical antiquity and modern times. The beginning and close of this period are not well agreed upon. It is usual, however, to regard the Middle Ages as beginning with the overthrow of the Western Roman Empire by the barbarians in the fifth century and ending at the close of the fifteenth century or the beginning of the sixteenth century. Some scholars prefer to regard the Renaissance (q.v.) as the beginning of modern history. By some, who prefer to use precise landmarks, the Middle Ages are made to extend from the deposition of the Roman Emperor by Odoacer in 476 to the fall of the Byzantine or Greek Empire in 1453, when Constantinople was taken by the Turks. Others again make the Middle Ages terminate with the discovery of America in 1492. The term Dark Ages formerly was frequently used to cover the greater part of the Middle Ages, the designation being applied by some to the period from the fifth to the eleventh century and by others made to embrace all but the last two centuries of the Middle Ages.

In 395 A.D. the Emperor Theodosius died, leaving two sons, one to rule in the West, the other at Constantinople. But in theory there was a single Roman Empire, embracing practically the whole Christian world, extending from the Atlantic to the Euphrates, from the Rhine and the Danube to the great Sahara, with a single government and the same system of laws. Christianity was the recognized state religion. The Roman civilization was in many respects uniform throughout the Empire; a great network of roads bound all the parts together. In the fifth century the Germanic barbarians overran the Western Empire and settled as conquerors in various parts. Thus the three most important factors which were to influence the civilization of western Europe during the early Middle Ages were the Roman, the Christian, and the German. The Roman civilization had absorbed much of Greek art, Greek literature, Greek philosophy, and Greek science. It had developed to a marvelous degree a system of administration and law. It had so completely assimilated the various races in the Western Empire that they were proud to be called Romans. The Christian Church had brought in high ideals and had taught new duties. But at the same time it exalted asceticism, and had a tendency to oppose everything pagan which conflicted with the teachings of the Church. Much of the classical literature and art was under the ban of the Church, because these were intimately associated with the pagan religions. Consequently the Church diminished the inheritance which the Middle Ages would otherwise have received. On the other hand, the Church adopted the magnificent Roman system of administration and thus became a great centralizing governmental force. The German barbarians contributed to the mediæval civilization certain ideas of freedom and of the im-

portance of the individual, as shown in their public assemblies, but the most important contribution was the Germans themselves, a strong race, capable of rapid advance, and always ready to assimilate itself to surrounding conditions. Furthermore, those who settled in the Empire were relatively few in number, and consequently were profoundly influenced by the more numerous population among which they dwelt.

The fifth and sixth centuries were marked by the migrations of the German nations. One tribe after another broke through the Roman frontier and carved out a territory for itself. By 600 almost the whole of the former Western Empire was in the power of the Germans. During the seventh and eighth centuries the Romanic population and the barbarians were going through a process of fusion. By 800 the two formed practically a homogeneous society of a composite nature. The civilization was far higher than that of the early Germans, far lower than that of the Romans. During this period the Church was converting and bringing under its authority the various peoples of the North and West. (See FRANKS.) Its monks were missionaries of culture and also political agents of great importance in binding the separate nations to Rome. From 800 there was again a Roman Empire in the West. (See CHARLES THE GREAT.) Although the Carolingian Empire soon disintegrated, its brief existence had been of great importance as a precedent and had had a lasting effect upon the relations between the Germans and the Roman Catholic church. In the states which arose with the disruption of the Frankish realm the absence of a strong central government threw each district upon its own resources. Local rulers arose, defended their territories against invaders, and maintained a semblance of order. These leaders were sometimes bishops or abbots, sometimes lay nobles. The power fell into their hands. (See FEUDALISM.) The Church was the only bond of union and the only restraining force in the disturbed conditions of the times. It became a mighty engine of government, whose interests were by no means restricted to religious matters. From this time until the close of the thirteenth century the Church was the most important factor in mediæval history. Its authority, wealth, and influence increased constantly; its members were prominent in every sphere of activity.

In the latter half of the tenth century Otho the Great (q.v.) more closely connected the fortunes of Germany and Italy by restoring the Empire of Charles the Great. His action was to result in weakness and disunion for both countries, but for three centuries the German monarch was apparently the leading power in western Europe. During this period the Normans (q.v.) conquered England, southern Italy, and Sicily, and strong monarchies began to develop in England, France, and Spain. Ever since the early part of the eighth century Christendom had been waging a fierce warfare against the Mohammedan power in the West. At the close of the eleventh century began a great onslaught of western Europe upon the Mohammedan power in the East, known as the Crusades (see CRUSADE). The broadening of the horizon, the resultant skepticism, and the enrichment of Europe, which resulted from the Crusades, caused the progress in many lines to be more rapid. The twelfth and thirteenth centu-

ries were periods of great intellectual activity, marked by the foundation of universities, the prevalence of heresy, the development of vernacular literatures, the rise of cities, and the growth of national feeling. The following centuries are generally designated the period of the Renaissance (q.v.).

It is difficult to describe the Middle Ages as a whole, because there was a constant evolution for over 1000 years. The characteristics which contrast most sharply with those of the classical world are these: in the Middle Ages the civilization as a whole was much ruder and mixed with barbaric elements; the individual was of greater importance than the state; men were dominated by a militant, vital religion. If contrasted with the modern period which followed, the Middle Ages were a period when the human intellect was restricted by a deference to the authority of tradition in every phase of life, a deference which was wholly at variance with a critical and skeptical attitude of thought. Again, the physical world, the world of investigation, the world of action, were very limited for the mediæval man. The discoveries at the close of the fifteenth century which disclosed new continents were coincident with the development of the printing press, the revolution in warfare due to the introduction of gunpowder, and the discoveries in the various sciences which opened new worlds of thought and activity. The important artistic activity of the Middle Ages falls into three distinct epochs, the Early Christian (see CHRISTIAN ART), Romanesque, and Gothic, under which titles the art of the period is treated.

MIDDLEBORO. A town, including several villages, in Plymouth Co., Mass., 35 miles by rail south by east of Boston, on the Nemaasket River and on four branches of the New York, New Haven, and Hartford Railroad (Map: Massachusetts, F 5). It has a public library, is an attractive summer resort, and is noted as an industrial centre. Its manufacturing interests are represented by several large shoe factories, woolen mill, paper-box factory, saw and planing mills, and varnish factories. The town receives the income of about \$500,000, bequeathed to it by Thomas S. Peirce, a former citizen. The government is administered by town meetings. Middleboro owns its gas and electric-light plants. Pop., 1900, 6885; 1910, 8214; 1914 (U. S. est.), 8778. Settled about 1662 on the site of an old Indian village. Nemaasket, Middleboro was incorporated in 1669. Consult Barber, *Historical Collections of Massachusetts* (Worcester, 1840), and Thomas Weston, *History of the Town of Middleboro* (Boston, 1906).

MIDDLEBURY. A village and the county seat of Addison Co., Vt., 34 miles north by west of Rutland, on the Rutland Railroad (Map: Vermont, B 4). The village is situated in the Otter Creek valley, near the Green Mountains, in a region of picturesque scenery. It is the seat of Middlebury College (q.v.), and has the Sheldon Art Museum and Library, a public library, and a fine courthouse and opera house; also attractive fair grounds. The industries are represented by agricultural interests and by several marble quarries, marble mills, limekilns, and flour, saw, door, sash, and pulp mills. The village possesses valuable water power. Under a revised charter of 1877 Middlebury village is governed by a board of trustees, chosen annually, who elect subordinate administrative officers. Pop. (village), 1900, 1897; 1910, 1904. Middlebury was founded in 1773, but, owing to threatened attacks from the English and the Indians, was almost completely deserted during the Revolutionary War. In 1813 it was incorporated as the borough, and in 1832 as the village of Middlebury. Consult Swift, *History of the Town of Middlebury* (Middlebury, 1859).

MIDDLEBURY COLLEGE. An institution for higher learning, founded at Middlebury, Vt., in 1800, and which is under no denominational control. The trustees are elected for life and are not restricted in the choice of their successors. The departments of instruction include French, German, economics, history, political science, pedagogy, philosophy, physics, mathematics, chemistry, biology, geology, home economics, drawing and surveying. The attendance in all departments in 1914-15 was 340, with 31 instructors. The original campus of the college, which was presented to the corporation by Col. Seth Storrs in 1810, was increased in 1909 by a gift from Col. Joseph Battall of 35 acres adjoining. This is used as a site for buildings

for women. In 1912 a further gift of 79 acres was received for the Porter Athletic Field. There are 13 buildings on the campus, of which the most important are Painter Hall (1815), Starr Hall (1861), the chapel (1836), Egbert Starr Library (1900), Warner Science Hall (1901), Hamlin Commons (1882), McCullough Gymnasium (1912), Music Hall (1913), and the Chemistry Building (1913). The State of Vermont in 1908 established a department of pedagogy for the training of high-school teachers, which department is sustained by an annual appropriation. Middlebury College was on the first list of accepted institutions of the Carnegie Foundation and has received a grant from the General Education Board. In 1915 the Mead Memorial Chapel was presented by John A. Mead, former Governor of the State. The college has been coeducational since 1883, but in 1902 a charter was granted by the Legislature authorizing the establishment by the corporation of a separate college for women. The grounds and buildings of the college are valued at \$430,000 and the entire property at \$1,070,000. The library contains about 45,000 volumes. The president in 1915 was John M. Thomas, D.D., LL.D.

MIDDLE C. In music, the note *c'*, which is on the first leger line below the treble staff,

, or above the bass staff . The C clef always represents the note termed middle C, and the lines and spaces above or below are designated accordingly. See **MUSICAL NOTATION, The Clefs.**

MIDDLE EAR, INFLAMMATION OF. See **OTITIS MEDIA.**

MIDDLE ENGLISH. See **ENGLISH LANGUAGE; ENGLISH LITERATURE.**

MIDDLE KINGDOM. A native name of China, believed by its inhabitants to be the middle point of the earth.

MIDDLE LATITUDE SAILING. See **SAILINGS.**

MID'DLEMARCH. A novel by George Eliot (1872). It appeared serially in *Blackwood's Magazine* in 1871. The author considered this story of a provincial town her greatest work. It consists of two stories, that of the Viney family and that of Dorothea Brooke, who is the chief character.

MID'DLESBORO. A city in Bell Co., Ky., 64 miles north by east of Knoxville, Tenn., and on the Louisville and Nashville and the Southern railroads (Map: Kentucky, G 6). It has considerable reputation as a summer resort, and contains a Carnegie library, the W. K. Evans Hospital, and commodious city hall and courthouse buildings. The chief industrial establishments include ironworks, coal mines, and a brewery. Pop., 1900, 4162; 1910, 7305.

MIDDLESBROUGH, mid'd'lz-b'rūh. A manufacturing town, port, and parliamentary and county borough in the North Riding of Yorkshire, England, near the mouth of the Tees, 48 miles north of York (Map: England, E 2). It is the centre of the Cleveland iron district, one of the largest in the world. The town is well built, with handsome specimens of architecture, including the town hall with library, a memorial museum, and a Roman Catholic cathedral. In the Royal Exchange, a fine building, the weekly iron market is held on Tuesdays, attended by persons connected with the iron trade from all

parts of the Kingdom, as well as foreigners. It is the headquarters of a Roman Catholic bishop. Albert Park, containing 72 acres, is tastefully laid out. The town owns its water, gas, abattoirs, markets, and cemeteries, and maintains baths, washhouses, and free libraries. Middlesbrough was founded in 1830. The opening of the docks in 1842 gave it additional importance. From the year 1852, when iron ore was discovered in the Eston Hills, the town increased rapidly and has acquired an important position as an iron-manufacturing centre, turning out over 2,500,000 tons per year of pig iron alone, and having smelting furnaces on an extensive scale, iron foundries, manufactures of rails, locomotive engines, tubes, boilers, wire, chemicals, salt, oil, and pottery. Shipbuilding is extensively carried on. There are spacious docks, and a breakwater nearly 2½ miles long. The harbor accommodates vessels with a draft of 32 feet. The tonnage entered and cleared, excluding coastwise vessels, was 3,225,000 in 1911. Middlesbrough was incorporated in 1853. Pop., 1901, 91,302; 1911, 104,767. Consult H. G. Reid, *Middlesbrough and its Jubilee* (Middlesbrough, 1881).

MID'DLESEX. The metropolitan county in the southeastern part of England, bounded north by Hertfordshire and south by Surrey (Map: England, F 5). Next to Rutland it is the smallest of the English counties, with an area of 283 square miles, 50 square miles of which comprises a part of metropolitan London. It is generally flat, being watered by the Thames, Colne, Lea, and Brent. Outside of London the land is chiefly devoted to grass and hay farms and to market gardens, the produce of which is sent to supply the metropolis. Capital, Brentford. Pop., 1901 (excluding the metropolitan area), 798,738; 1911, 1,126,465.

MIDDLE TEMPLE. One of the four great guilds or societies of barristers in England, known as Inns of Court. The Inns of the Middle Temple are so called from the group of ancient buildings in London occupied by them, which were the seat of the Knights Templars and passed into the hands of the lawyers after the dissolution of that famous order of chivalry. They are grouped with the buildings of the three other Inns near the Law Courts. See **INNS OF COURT.**

MIDDLETON. A municipal borough and market town in Lancashire, England, in the valley of the Irk, 6 miles north of Manchester (Map: England, D 3). Its chief industries are the manufacture of cotton, silk, soap, chemicals, and machinery. Much coal is mined near by. It has a fifteenth-century church, a grammar school dating from 1572, a fine town hall, and a technical school. The municipality owns gas works, electric-lighting plant, markets, and public baths, and maintains free library, park, recreation grounds, and a sewage farm. Pop., 1901, 25,180; 1911, 27,980.

MIDDLETON, ARTHUR (1681-1737). An American colonist, born in South Carolina. He was educated in England. After his return to his native Colony he was elected a member of the Commons House, was appointed naval officer for the Colony (1711), member of the Provincial Council (1711-17), and afterward Speaker of the Commons. In 1719 he was president of the convention which took the government of the Colony away from the Lords and placed it directly under the crown. Later he became

president of His Majesty's Council, and as such was acting Governor from 1725 until the arrival of the first regularly appointed royal Governor in 1731. Middleton was an uncompromising supporter of the royal authority.

MIDDLETON, ARTHUR (1742-87). A signer of the Declaration of Independence, grandson of Arthur Middleton (1681-1737). He was born in South Carolina. In 1754 he went with an uncle to England, where he was educated at Harrow, Westminster School, and St. John's College, Cambridge. He returned to South Carolina in 1763, settled at Middleton Place, on Ashley River, became a justice of the peace, and from 1765 to 1766 served in the Commons for St. Helena. He then again went abroad and spent three years in England and southern Europe. On his return in 1772 he was again elected to the Commons, and in 1774 became a member of the Upper House of the Provincial Congress. He was one of the ablest and boldest opponents of the royal authority, and early in 1775 became a member of the Secret Service Committee and in June of the same year of the Council of Safety. Early in 1776 he helped frame a constitution for the State, and later in the same year he was sent as a delegate to the Continental Congress and signed the Declaration of Independence. In 1778 he was elected a member of the State Legislature and was also chosen Governor and commander in chief of South Carolina, but refused to serve. He assisted in the defense of Charleston, and upon the capture of that place was imprisoned in St. Augustine and later in the prison ship *Jersey*. Being exchanged in July, 1781, he was again elected to the Continental Congress, where he served until peace was declared. Later he became a member of the State Senate and a trustee of Charleston College. Middleton was a man of much energy and judgment, an able debater, and a forceful writer. Under the pseudonym of "Andrew Marvel" he wrote a number of effective political essays; he also left stenographic reports of many of the debates in which he participated.

MIDDLETON, CONYERS (1683-1750). A divine of the Church of England. He was born Dec. 27, 1683, at York or Richmond in Yorkshire. He studied at Cambridge, where he took the degree of B.A. in 1702, was elected a fellow in 1706, and shortly after married a lady of fortune. The views he expressed and defended were generally such as to draw down upon him the imputation of being an "infidel in disguise," though some of them—such as that the Jews borrowed some of their customs from Egypt, that the primitive writers in vindicating Scripture found it necessary sometimes to recur to allegory, and that the early stories of Genesis are not literal history—are now commonly held. Middleton died at Hildersham in Cambridgeshire, July 28, 1750. His controversial writings are acute, but marred by bitterness. His principal writings are: *A Letter from Rome, Showing an Exact Conformity between Popery and Paganism; or the Religion of the Present Romans Derived from that of their Heathen Ancestors* (1729), which provoked the most violent indignation among Roman Catholics, and *The History of the Life of M. Tullius Cicero* (2 vols., 1741). All his pamphlets, treatises, etc., were collected and published under the title of *Miscellaneous Works* (4 vols., London, 1752). Consult Leslie Stephen, *English Thought in the Eighteenth Century* (London, 1876).

MIDDLETON, SIR FREDERICK DOBSON (1823-98). A British soldier. He was born in Belfast, Ireland, and, graduating at the Royal Military College at Sandhurst in 1842, saw active service in New South Wales, New Zealand, Burma, and India. In the Indian Mutiny (1857-58) he was decorated with the Victoria Cross for gallant conduct. In 1808 he accompanied his regiment to Canada, but returned to England in 1870. In 1884 he returned to Canada as commander in chief of Canadian militia, and in 1885 he energetically suppressed the Riel rebellion in the Northwest, for which he received from the Canadian Parliament a grant of \$20,000 and the honor of knighthood from the Queen. In 1890 he returned to England, and in 1896 was appointed keeper of the crown jewels.

MIDDLETON, GEORGE (1880-). An American playwright, born at Paterson, N. J. He graduated from Columbia University in 1902. In 1911 he married Fola La Follette, an actress and writer, the daughter of Robert M. La Follette (q.v.), and a year later became literary editor of *La Follette's Weekly*. His plays, several being dramatized novels, include: *The Cavalier* (1902), with Paul Keater; *The Wife's Strategy* (1905); *The Sinner* (1907); *The House of a Thousand Candles* (1908); *Rosalind at Red Gate* (1910); *The Enemy* (1911); *The Prodigal Judge* (1913). He published: *Embers* (1911), *Tradition* (1913), and *Possession* (1915), all three volumes containing one-act plays; and *Noiradays* (1914), a comedy.

MIDDLETON, HENRY (1717-84). An American patriot, born in South Carolina, a son of Arthur Middleton (1681-1737). He was elected to the Commons and served as Speaker of that body in 1745-47 and in 1755-70 he was a member of the Council. He was a delegate to the Continental Congress (1774), serving as president of that body from October of that year to May, 1775. He was also president of the Provincial Congress of South Carolina in 1775-76, and was one of a committee of 11 to prepare a plan of government until the dispute between Great Britain and the colonies could be settled; was elected a member of the Legislative Council in 1776, later of the Council of Safety, and was chosen to the Senate of South Carolina under the new constitution of 1778. He was a wealthy planter and slave owner and a man of marked public spirit.

MIDDLETON, HENRY (1771-1846). An American statesman and diplomat, the son of Arthur Middleton (1742-87). He was born in Charleston, S. C., was carefully educated by private tutors and at South Carolina College, and in 1801 was elected to the South Carolina Legislature, where his brilliant powers as an orator attracted wide attention and led, in 1810, to his election as Governor of the State. He held this office until 1812, was a strong supporter of the war policy of the Madison administration, and in 1815, after a brief retirement from politics, was elected to Congress, serving until 1820. In that year he was appointed by President Monroe Minister of the United States to Russia, where in a service of 10 years he did much to strengthen the commercial relations between the two nations, negotiating in 1824 the first treaty which provided for the regulation of trade and fisheries in the Pacific. On his return to America in 1830 he retired from public life.

MIDDLETON, JOHN HENRY (1846-96). An English classical scholar, born at York. He studied at Cheltenham College and at Exeter College, Oxford, but ill health prevented his graduating. During this period he read widely in the fields of art and archæology. Afterward he traveled in various parts of the world and returned to become a partner of his father (an architect) at Westminster. In 1886 he was elected Slade professor of fine art at Cambridge, where three years later he became director of the Fitzwilliam Museum. Appointed art director of the South Kensington Museum, London, he carried out various important reforms. He wrote *Ancient Rome* (1885; rev. ed., 1888) and *The Remains of Ancient Rome* (2 vols., 1892), valuable works, giving among other things an excellent account of the building materials used by the Romans and of their methods of constructing walls, arches, buildings, etc. Middleton also published descriptions of collections in the Fitzwilliam Museum.

MIDDLETON, THOMAS (?1570-1627). An English dramatist, born probably in London. Hardly a detail of his life is known. He seems to have studied law, and may thus be one of the two Thomas Middletons entered at Gray's Inn in 1593 and 1596. It is thought that he began writing for the stage as early as 1599, but the first mention of him is in Henslowe's *Diary*, on May 22, 1602. He was then collaborating with Munday, Drayton, Webster, and others on a lost play called *Cæsar's Fall*. In this year he published a comedy entitled *Blurt, Master-Constable*, and in 1603-04 two prose tracts, *The Black Book* and *Father Hubbard's Tales*, lively and highly colored satirical sketches of London life. Between this time and his death he wrote more than 20 plays and 12 masques and pageants. In 1620 he was made chronologer to the city of London. He died in London near July 1, 1627. He was successful in both comedy and tragedy. His humor is seen at its best in *A Trick to Catch the Old One* (1608); *The Roaring Girl* (1611); *The Spanish Gypsy*, a tragi-comedy (acted as early as 1623, but not printed till 1663); *A Chaste Maid in Cheapside* (not printed till 1630). All except the third in this list depict contemporary London life. The second has as heroine the notorious Mary Frith, known as Moll Cutpurse. Middleton's dramatic power is at its height in *Women Beware Women* (first printed in 1657). It is a romantic tragedy founded in part on the history of Bianca Capello. Almost equal to this play are *The Spanish Gypsy*, cited above, and *The Changeling* (printed 1653), considered by some the most powerful of all the plays with which Middleton's name is connected. *A Game at Chess*, a political drama, attacking Spain, aroused such enthusiastic hatred that the Spanish Ambassador protested, and the piece was taken off the stage after scoring a great success (1624). A play called *The Witch* (printed 1778) is of considerable interest because it has the same motive as Shakespeare's *Macbeth*. Middleton is in the forefront of the group of greater Elizabethan dramatists, and there is little, outside the work of Shakespeare himself, which can match the best of his scenes, tragic or comic. The lack of care evident in his plays makes it impossible for them to take the highest rank. Consult: *Works*, edited by Alexander Dyce (5 vols., London, 1840); *Works*, edited by A. H. Bullen (8 vols., ib., 1886);

selections from the plays, edited by Havelock Ellis, with an introduction by Swinburne, for the "Mermaid Series" (ib., 1887); P. G. Wiggins, *Inquiry into the Authorship of the Middleton-Rowley Plays* (Boston, 1897); D. H. Jung, "Das Verhältnis Thomas Middletons zu Shakespere," in *Münchener Beiträge zur romanische und Englische Philologie* (Munich, 1904); F. G. Fleay, *Biographical Chronicle of the English Drama, 1559-1642* (2 vols., ib., 1891); A. W. Ward, *History of English Dramatic Literature* (rev. ed., New York, 1899).

MIDDLETON, THOMAS FANSHAW (1769-1822). Bishop of Calcutta. He was born in Kedleston, Derbyshire, England; was educated at Christ's Hospital, and graduated at Pembroke College, Cambridge, in 1792; was ordained to a curacy in Gainsborough in 1792, and in 1795 became rector at Tansor, Northamptonshire, and in 1802 at Bytham, Lincolnshire. He exchanged these in 1811 for the curacy of St. Pancras, London. In 1814 he was consecrated first Bishop of Calcutta, where he did much to promote the advancement of Christianity and education, founded the Bishop's Mission College in 1820, and established a consistory court. He was editor for short periods of the *Country Spectator* at Gainsborough and the *British Critic* (new series) in London. The work by which he was best known was that on *The Doctrine of the Greek Article Applied to the Criticism and Illustration of the New Testament* (1808). Consult C. W. Le Bas, *Life of Bishop Middleton* (London, 1831).

MIDDLETOWN. A city and the county seat of Middlesex Co., Conn., 16 miles south of Hartford, on the Connecticut River and on the New York, New Haven, and Hartford Railroad and the line of the Hartford and New York Transportation Company (Map: Connecticut, E 3). It is connected with the opposite town of Portland, known for its brownstone quarries, by an unusually long drawbridge. Middletown is the seat of Wesleyan University (q.v.); the Berkeley Divinity School (Protestant Episcopal), opened in 1854; the State Hospital for the Insane; and the State Industrial School for Girls. Other features are the municipal building, Middlesex Hospital, and the Russell Free Library. The city has considerable trade, as the river is navigable as far as Hartford for light-draft steamers, thus increasing the transportation facilities. Middletown is also an important industrial centre, with manufactures of cotton webbing, hammocks, pumps and pump machinery, marine hardware, locks, woolen blankets, dress shields, canopies, belting, paper boxes, electrical appliances, toys, boots and shoes, chemicals, silver-plated ware, rubber, bone, silk goods, etc. There are valuable mineral deposits in the vicinity, and the region is rich in fruit and tobacco. Middletown is governed, under a charter of 1882, by a mayor, elected biennially, and a city council, chosen on a general ticket. The water works are owned and operated by the municipality. Pop., 1910, 11,851; 1914 (U. S. est.), 12,815.

Founded in 1650 and incorporated as a town under the name of Mattabeseck in 1651, Middletown received its present name in 1653 and was incorporated as a city in 1784. Previous to the Revolution and for some time thereafter it was a very important commercial port, a large number of its citizens being engaged in the West Indian trade. For many years prior to 1886,

when the Custom House was moved to Hartford, it was a port of entry. Consult: Whittemore, *History of Middlesex County, Connecticut* (New York, 1884); an article on "Middletown," in the *Connecticut Quarterly* (Hartford, 1898); C. C. Adams, *Middletown Upper Houses: A History of the North Society of Middletown from 1650 to 1800* (New York, 1908).

MIDDLETOWN. A town in Newcastle Co., Del., 25 miles south-southwest of Wilmington, on the Philadelphia, Baltimore, and Washington Railroad and on the Appoquinomink River. (Map: Delaware, H 2). It has considerable fruit-canning interests, owing to its location in the noted fruit-growing belt of the State, also creameries and vegetable canneries, and manufactures farming implements, shirts, etc. There are municipal water works and an electric-light plant. Pop., 1900, 1587; 1910, 1399.

MIDDLETOWN. A city in Orange Co., N. Y., 67 miles northwest of New York City, near the Wallkill River and on the Erie, the New York, Ontario, and Western, and the Middletown and Unionville railroads (Map: New York, Insert A 1). It is the seat of a State Hospital for the Insane, the largest homœopathic institution in the United States, and has a public library and fine high-school and Federal buildings. The centre of an agricultural and dairying district, Middletown enjoys a considerable trade in the products of the region; and among its industrial establishments are straw-hat factories, car shops (N. Y., O., and W.), saw and file works, cigar factories, a tannery, a milk condensery, and manufactures of shirts, automobile tires, wrapping machines, and cut glass. The city owns and operates the water works. Pop., 1900, 14,522; 1910, 15,313; 1914, 15,650 (excluding over 2000 State Hospital patients); 1920, 18,420. Settled before the Revolution and named from its central location between Montgomery and Mount Hope, Middletown was incorporated as a village in 1848 and was chartered as a city in 1888. Its situation as the halfway station between the Hudson and the Delaware rivers, on the old Minisink road leading to the "far West" of New York State, made it of considerable importance in the later years of the eighteenth and the early years of the nineteenth century; while its position as a terminal of the Erie Railroad and the consequent establishment of a foundry about 1845 gave it a start as an industrial centre.

MIDDLETOWN. A city in Butler Co., Ohio, on the Miami River and the Miami and Erie Canal, 34 miles north of Cincinnati, on the Cleveland, Cincinnati, Chicago, and St. Louis, the Cincinnati, Hamilton, and Dayton, the Cincinnati Northern, and other railroads (Map: Ohio, B 7). It has a public library, a hospital, a government building, and a fine opera house; and there are extensive manufactures of tobacco, paper, bicycles, steel, steel sheets, iron, motor cycles, paper machinery, gas engines, and paper boxes and bags. The water works are owned by the municipality. Middletown was settled as early as 1794, and in 1913 adopted the commission form of government. Pop., 1900, 9215; 1910, 13,152; 1914 (U. S. est.), 14,827; 1920, 23,594.

MIDDLETOWN. A borough in Dauphin Co., Pa., 9 miles southeast of Harrisburg, on the Susquehanna River and on the Pennsylvania and the Philadelphia and Reading railroads (Map: Pennsylvania, H 7). It is in a farming region

and has flouring and planing mills, stove works, car shops, and shoe, hosiery, cigar, and furniture factories, the products of which constitute a considerable export trade. The electric-light plant is owned by the municipality. Middletown was founded in 1755 and was incorporated as a borough in 1828. Pop., 1900, 5608; 1910, 5374.

MIDDLE TOWN INDIANS. See MIWOK STOCK.

MIDDLE VOICE. See DEPENDENT; GRAMMAR, near the end.

MIDLINGS. See FLOUR.

MIDEWIN, mē'dē-wīn, or **MIDEWIWIN,** mē'dē-wē'wīn, or **MIDE,** mē'dē, **SOCIETY.** A secret organization found among many Algonquian (q.v.) Indian tribes, consisting of progressive degrees or ranks having some vague resemblance to the Masonic ritual. In the public initiation ceremonies the candidates spit up shells as proof of their having been magically shot into their bodies, or symbolic of the spiritual influence of the ritual. Consult W. J. Hoffman, in *Bureau of American Ethnology, Seventh Annual Report* (Washington, 1891).

MIDGE (AS. *mycg*, OHG. *mucco*, Ger. *Mücke*, Icel. *my*, midge, fly; connected with Gk. *μια*, *myia*, fly). The popular name of the little flies of the family Chironomidae, applied also in Europe to the Simuliidae, which in this country are called black flies and buffalo gnats. There is nothing very specific in the use of the name, and it is generally applied to almost any minute flying insect, most of which are true flies.

MIDHAT PASHA, mē'd'hāt' pā-shā' (1822-84). A Turkish statesman, born in Constantinople. His origin was humble, but his marked ability secured him rapid promotion in the Ottoman civil service. He visited England and France; was made a Pasha; governed Bulgaria and other provinces with energy and wisdom; and in 1872 was named Grand Vizier. He had already identified himself with the progressive party known as Young Turkey and was disliked and feared by the reactionaries. He took a leading part in the conspiracy which led to the dethronement of Abd-ul-Aziz (May 30, 1876) and was made Grand Vizier, Dec. 20, 1876, by Abd-ul-Hamid II, but was dismissed and banished in February, 1877. A constitution which he had promulgated failed. Later he was permitted to return, and became Governor of Syria and then of Smyrna. In 1881 he was tried, with others, upon the charge of murdering Abd-ul-Aziz and was condemned to death, but the sentence was commuted to perpetual banishment when Great Britain interfered. He died in Arabia, May 8, 1884. He was the author of *La Turquie, son passé, son avenir* (Paris, 1878); Consult: B. Brunswick, *La vérité sur Midhat Pasha* (Paris, 1877); L. A. Léouzon Le Duc, *Midhat Pasha* (ib., 1879); Ali Haydar Midhat, *The Life of Midhat Pasha: A Record of his Services, Political Reforms, Banishment, and Judicial Murder* (London, 1903).

MIDIANITES, mid'i-an-īts. The name of a Semitic people. According to Gen. xxv. 2, Midian, the eponymous ancestor, is a son of Abraham through his wife Keturah. That the Midianites are to be reckoned with the Arabs is clear. We find them now at Mount Sinai (Ex. iii. 1), again to the east of Israel (Gen. xxv. 4); in the days of Gideon they advance from the Syrian Desert (Judg. vi), and in Num. xxv. 6-9 they are represented as occupying a portion of Moab. They were evidently in the

main a nomadic people whose general habitat was a region including the northern portion of Hejaz and the fringe of the Syrian Desert east of Edom and Moab. The Midianites east of the Gulf of Akabah seem to have been a pastoral people, while those farther north, whose attacks are described in Judges vi-viii, make the impression of Bedouin hordes. According to Ex. iii. 1, Moses's father-in-law, Jethro, was a Midianitish priest. Grimme has suggested that Midian is mentioned under the form Midhi in a Minæan inscription (Halevy, 535; Glaser, 1155). The land of Midian extended northward from Horeb, or Sinai, close to the eastern shore of the Gulf of Akabah. A place called Madiana is mentioned by Ptolemy close to the Red Sea and about opposite the extremity of the Sinaitic Peninsula, and no doubt this stands in some relationship in the original application of Midian in the Old Testament. Consult: R. F. Burton, *Gold Mines of Midian* (London, 1878); .d., *Land of Midian Revisited* (2 vols., ib., 1878-79); Grimme, *Die Weltgeschichtliche Bedeutung Arabiens: Mohammed* (Munich, 1904).

MIDLAND. A town in Simcoe Co., Ontario, Canada, on Georgian Bay and on the Grand Trunk Railway (Map: Ontario, E 4). A line of steamboats runs to Parry Sound. Midland's industrial establishments include three grain elevators, four lumber mills, a blast furnace, iron smelters, woolen and flour mills, engine works, a box factory, a shipbuilding yard, and foundry and machine shops. Power for manufacturing is supplied from the Severn River. Pop., 1901, 3174; 1911, 4663.

MIDLAND. A city and the county seat of Midland Co., Mich., 20 miles northwest of Saginaw, at the junction of the Tittabawassee and Chippewa rivers and on the Pere Marquette and Michigan Central railroads (Map: Michigan, E 5). It has large chemical factories, cement-block works, and a tile factory. The water works are owned by the city. Pop., 1900, 2363; 1910, 2527.

MIDLETON, ninth VISCOUNT. See BRODRICK, WILLIAM ST. JOHN FREMANTLE.

MID-LOTHIAN, mid-ló'thri-an. A county of Scotland. See EDINBURGHSHIRE.

MIDNAPUR, mid'ná-poor. The capital of a district of Bardwan, Bengal, British India, on the Kasai River, 68 miles by rail west of Calcutta, with which it is also connected by a canal (Map: India, F 4). It is an educational centre, with a municipal arts college, high school, public library, central jail, and printing establishments, and is also the seat of an active American missionary settlement. It has manufactures of cloth, baskets, mats, oil, copper, brass, silk, indigo, and timber, and an important trade in rice. Pop., 1901, 33,140; 1911, 32,740.

MIDNIGHT APPOINTMENTS. In American history, a term applied to the court officials appointed under the Act of February, 1801, by John Adams on the last night of his administration as President. The commissions were signed but left undelivered in the executive offices.

MID'RASH (Heb., from *dárash*, to seek, search). The general name given to the exposition of the Old Testament among the Jews. The prohibitions and ordinances contained in the Pentateuchal codes were specified and particularized according to certain hermeneutical rules, and further surrounded by traditional ordinances and inhibitions. This division of Midrash is represented by the Halacha (q.v.),

the binding authoritative, civil, and religious law as laid down in the Talmud. Another branch of the Midrash, however, is the Haggada (q.v.), a kind of free poetical homiletics on the whole body of the Old Testament, and the term Midrash without further specification generally refers to this branch of rabbinical literature. The chief collections of this part of the Midrash are *Midrash Rabba* or *Midrash ha-gadol* (on the Pentateuch and the five scrolls) and *Pesikta* to various sections of the Bible. Besides this there are Midrashim to the separate books of the Pentateuch, Exodus, Leviticus, Numbers, and Deuteronomy.

Fiebig, *Jüdische Wundergeschichten in des neutestamentlichen Zeitalters* (ib., 1911).

MID'RIFE. The diaphragm (q.v.).

MID'SHIP'MAN. In the United States and British navies *midshipman* is the lowest grade of line or executive officers. The title originated in the British navy more than 200 years ago and was derived from the fact that the "young gentlemen" on British men-of-war who were under instruction for the purpose of becoming officers were given quarters *amidships* abreast the mainmast on the lower deck. When the navy of the American Colonies was organized, the practice of the British service was followed as regards this and other ranks. Previous to the Civil War, midshipmen who had finished their course of instruction were called *passed midshipmen* until promoted. A few years after the war the title of midshipman at the Naval Academy, and on probation at sea for two years afterward, was changed to *cadet midshipman*. In 1882 it was changed to *naval cadet*, but in 1902 the title of midshipman was restored. For many years midshipmen served two years at sea after graduation, but now they are commissioned as ensigns as soon as they leave the Academy. See CADET; NAVAL ACADEMY.

MIDSHIPMAN. See SAPO.

MIDSHIPMAN EASY, MR. A story by Frederick Marryat (1836).

MIDSHIPMAN'S BUTTER. See AVOCADO.

MIDSHIPMAN'S HITCH. See KNOTTING AND SPLICING.

MIDSUMMER EVE. See SAINT JOHN'S EVE.

MIDSUMMER NIGHT'S DREAM, A. A comedy by Shakespeare, written about 1595, printed in 1600, when two editions appeared, by Thomas Fisher and by James Roberts, the latter being used for the folio reprint. It is evidently a masque or festival play and is a jumble of classic, mediæval, and fairy lore. The parts of Theseus and Hippolyta may have been taken from Chaucer's "Knight's Tale," but more probably from North's translations of Plutarch's "Theseus" (1579). Pyramus and Thisbe, drawn from Ovid's *Metamorphoses*, may have come

through Chaucer's *Legend of Good Women*, or was based on Robinson's *Handfull of Pleasant Delights*. Oberon, originating in the French *Huon of Bordeaux* in the Charlemagne cycle, is found in Greene's *James IV* (1500). Titania, without the name, can be traced to Chaucer's "Wife of Bath's Tale." Puck is the Robin Good-fellow of old English folklore. The rest of the fairy scenery is Shakespeare's own, except for a slight debt to John Lyly.

MIDWAY ISLAND. An atoll in lat. 28° 14' N. and long. 177° 23' W. discovered July 5, 1859, by Capt. N. C. Brooks of the *Gambia* and proclaimed American under the name Brooks Islands, formally annexed and named Midway in September, 1867, by the U. S. S. *Lackawanna*, at which time the Pacific Mail Steamship Company planned a coaling station. Since 1903 it has been continuously occupied as a relay station of the Commercial Pacific cable between Honolulu (1254 miles) and Guam (2593 miles). The atoll is pear-shaped, 2½ miles in its longer dimension, and has two inlets available for small vessels. Its coral wall carries two sandy islets, Middle Brooks or Eastern Island, 15 feet high and 1 mile long, and Lower Brooks or Sand Island, 55 feet high and ½ mile long. The cable superintendent is a game warden of the Pacific bird reservation. The atoll has been the scene of many wrecks, the most important being the stranding of the mail steamer *Mongolia* Sept. 15, 1906, without loss of life or property. The cable company now maintains a light. Consult "Correspondence Relative to Legislation for Relief of Midway Islands," in 58th Congress, Third Session, *Senate Document 183* (Washington, 1905); and Churchill, "Midway Island" in the *Sun* (New York, March 10, 1912).

MIDWIFE and MIDWIFERY. See OBSTETRICS.

MIDWIFE FROG, or OBSTETRICAL TOAD. A smooth toadlike terrestrial frog (*Alytes obstetricans*) of the family Discoglossidæ, found along the Mediterranean coast, and numerous and ubiquitous. From March to August the double call-note of the male, sounding like a

MIDWIFE FROG.

small bell, is heard, but it is difficult to see the performer. The remarkable feature of this frog's life, however, is its egg nurture. When the female is ready to extrude her eggs, which are of large size and attached to one another, in two rosary-like strings, to the number of several dozen, the accepted male mounts upon her back. During the expulsion of the eggs

they are fecundated by the male, who then pushes his hind limbs through the tangled mass, after which he releases the female, and returns to his hole dragging with him the burden, wrapped about his legs. He comes out each night to feed and to moisten the eggs in the dew or the nearest puddle, and after about three weeks, when the eggs are nearly ready to hatch, he takes them into the water, where he remains until the tadpoles escape through the softened envelopes. Broods born in early summer mature the same autumn, but later broods remain as tadpoles until the following May. A second species (*Alytes cisternasi*), of similar habits, occurs in Central Spain and Portugal.

MIELATZ, mé'látz, CHARLES FREDERICK WILLIAM (1860-). One of the foremost American etchers and lithographers. He was born in Breddin, Germany, and came as a boy to the United States. He studied drawing in the Chicago School of Design, and painting under F. Rondel in New York. As a teacher of etching in the National Academy of Design, of which he became an associate member, he exercised a powerful influence upon the younger generation, and for a long time was secretary of the New York Etching Club. Although a master of many techniques, adopting or combining those best suited to the subjects represented, he never parades his craftsmanship. Much of his later work was done in color. His art is virile, his line clean cut and energetic, his presentation fresh and original. He is chiefly known as an etcher of picturesque and interesting views of New York City; such as "The Naval Arch"; "Coenties Slip," a color print; "Entrance to Brooklyn Bridge"; the "Battery"; "In the Bowery"; "New York from Brooklyn Bridge"; "Poe Cottage, Fordham," a large and imposing print; "A Pell Street Balcony," a soft ground etching in color; "High Bridge," a lithograph. For the Society of Iconophiles he designed three important series of lithographs representing views in New York City, one of them after quaint old subjects in Staffordshire ware, printed in blue ink. Among his other works are "The Wave," an aquatint in green and yellow; "Winter Night," an aquatint; "Flowers," a dry point; and "The Passing Storm." His latest important works include a series of etchings of Georgian Court, Lakewood, N. J.

MIEB, myár. A Mexican town, situated on the Rio Grande, 110 miles in a straight line from its mouth (Map: Mexico, J 4). It is noted in connection with an attempted invasion of Mexico by Texans in 1842. Pop., 4000.

MIERES, myá'rás. A mining town of north Spain in the Province of Oviedo. It is situated 9 miles southeast of the city of Oviedo, among forest-covered mountains, and is surrounded by gardens and orchards. It has a score of mines and extensive factories for iron and chemical products. In the neighborhood are important mines of coal, iron, and cinnabar. Pop., 1900, 17,867; 1910, 27,866.

MIEREVELT, mé're-vélt, MICHEL JANSZON VAN (1567-1641). A Dutch portrait painter. He was born at Delft, and studied under Willem Willemsz and A. van Montfoort, called Blocklandt. Mierevelt was the court painter of the house of Orange, and attained celebrity. His portraits are simply and correctly painted and well characterized, but are somewhat cold and hard. Many inferior copies by pupils are also signed by his name. Among his best-known

works are William the Silent and other princes of Orange-Nassau, in the Rijks-Museum, Amsterdam; the poet Jacob Cats (ib.); and Oldenbarneveldt (Louvre). He is also represented by portraits in the galleries at The Hague, Dresden, London, Berlin, and in the Metropolitan Museum, New York. In the hospital at Delft is the "Anatomy Lesson," designed by him and executed by his son and pupil Pieter (1596-1623).

MIERIS, mē'ris. A family of Dutch painters. **FRANS VAN MIERIS, the elder** (1635-81), a genre painter, was born in Leyden, and was a pupil of Torenvliet, of Gerard Dou, and of Adriaen van den Tempel. His pictures are characterized by elegance of line; the color is clear, delicate, and rich, especially in painting velvets, satin, and other rich stuffs. The treatment is too superficial and smooth, however, to be strong. His principal works include the "Lady in the Crimson Jacket," National Gallery, London; "Lady at her Toilet," "Two Ladies Drinking Tea," "Interior of a Household," and a "Male Portrait," in the Louvre; "Boy Blowing Soap-Bubbles" and "The Artist and his Wife" (1663), in The Hague Museum; "Lady Writing a Letter" (1680) and "Lady Playing the Lute," Amsterdam Museum; the "Smoker" (1662) and a "Woman Fainting," Munich Gallery; the "Tinker" and many others in the Dresden Gallery.—**JAN VAN MIERIS** (1660-90), a genre and portrait painter, son and pupil of Frans the elder; he studied also under Lairese. Examples of his work are an "Assembly of Ladies and Gentlemen with a Lute-Player," Gotha Museum; "Surgeon Dressing a Wound," Hermitage, St. Petersburg.—**WILLEM VAN MIERIS** (1662-1747), a genre and mythological painter and sculptor, was born in Leyden, the son and pupil of Frans the elder. His work represents the school in its decline, and is inferior to his father's in drawing and impasto. He also modeled statuettes and vases adorned with bas-reliefs. Among his works are the "Trumpeter," the "Poultry Dealer," and the "Merry Toper," all in the Dresden Gallery.—**FRANS VAN MIERIS, the younger** (1689-1763). A genre painter and writer. He was the son and pupil of Willem, and a distinguished antiquary, and published works of merit on numismatics and history. His books include the *Historie der nederlandsche vorsten* (1732-35) and *Groot charterboek der graven van Holland, van Zeeland en heren van Vriesland* (1753-56). Among his paintings, which are of an inferior order, are the "Pharmacy" (1714), Amsterdam Museum; portrait of his father (1737), Copenhagen Gallery; and the "Fishmonger" (1747), Rotterdam Museum.

MIEROSLAWSKI, myē'rō-slāf'skē, LUDWIK (1814-78). A Polish revolutionary leader, born at Nemours, France. He was the son of a Polish officer in the service of France, received his education at the military school in Kalisz, and joined the Polish insurgents in 1830. Mieroslawski distinguished himself greatly, and was made an officer, serving until the fall of Warsaw, when he settled in Paris. Here he published a number of books in Polish and French, the most significant of which are: *Histoire de la révolution de Pologne* (vols. i-iii, Paris, 1837; iv-v, 1878); *The Revolution in Posen* (in Polish, ib., 1853). In 1846 he was at the head of another revolutionary movement in Poland, which resulted in his being captured and sentenced to death. From this fate he was rescued by the

outbreak of the general revolutionary movement of 1848. After fighting in Posen, Mieroslawski resigned his command in the face of ultimate defeat. In 1849 he participated in the revolutionary movement in Sicily, and after resigning his command placed himself at the head of the revolutionary army in Baden, but eventually retired to Paris. His last appearance as a revolutionist was in Poland in 1863, and, after the failure of that attempt, he spent the last years of his life writing political pamphlets. He died in Paris, Nov. 23, 1878.

MIFFLIN, FORT. See FORT MIFFLIN.

MIFFLIN, GEORGE HARRISON (1845-1921). An American publisher, member of the firm of Houghton, Mifflin & Company. Born in Boston, and educated at Harvard, he became connected with the publishing house of Hurd and Houghton (1867) and with the Riverside Press; he was admitted to the firm in 1872, and continued a partner in the succeeding firms of Houghton, Osgood & Company (1878-1880) and Houghton, Mifflin & Company (1880-1908). After 1908 he was president of the last-named company. He became president also of the Riverside Press, Cambridge, Mass.

MIFFLIN, LLOYD (1846-1921). An American poet, born at Columbia, Pa. He studied painting under his father, J. Houston Mifflin, a portrait painter and writer of verse, under Thomas Moran (1868-69), and later in Italy and Germany (1870-72). His work was exhibited in the United States, but failing health having forced him to abandon painting he turned to the writing of poetry. Among his numerous volumes of verse are: *At the Gates of Song* (1897); *The Slopes of Helicon, and Other Poems* (1898); *Echoes of Greek Idyls* (1899); *The Fields of Dawn and Later Sonnets* (1900); *Catalian Days* (1903); *The Fleeing Nymph and Other Verse* (1905); *Collected Sonnets* (1905); *Toward the Uplands* (1908); *Flower and Thorn* (1909).

MIFFLIN, THOMAS (1744-1800). An American soldier and statesman. He was born at Philadelphia, of Quaker parentage. He graduated at Philadelphia College in 1760, was a member of the Pennsylvania Legislature in 1772 and 1773, and in 1774 was sent as a delegate to the Continental Congress. Entering the army as a major in 1775, he became Washington's first aid-de-camp with the rank of colonel; was made quartermaster-general in August, 1775; and finally (Feb. 19, 1777) was promoted to the rank of major general and appointed a member of the Board of War. During the retreat from Long Island he commanded the covering party, and afterwards rendered valuable service by rousing the people to enlist, bringing essential aid to General Washington before the battles of Trenton and Princeton. Becoming dissatisfied with Washington's management of the war, he intrigued for his removal, forming with Conway and others the so-called "Conway Cabal" (q.v.), on the failure of which he was replaced (March, 1778) by Nathanael Greene as quartermaster-general, and in October, 1778, was removed from the Board of War. He was elected to Congress in 1782 and became its President the following year. He was a member and Speaker of the Pennsylvania State Legislature in 1785, and a delegate to the Constitutional Convention of 1787. From 1788 to 1790 he was President of the Executive Council of Pennsylvania, and from 1790 to 1799 was the first Governor of the State,

As such he took a conspicuous part in the suppression of the Whisky Insurrection, assuming personal command of the Pennsylvania militia. Consult: Simpson, *Eminent Philadelphians* (Philadelphia, 1859); J. H. Merrill, *Memoranda Relating to the Mifflin Family* (ib., 1890); William Rawle, "Sketch of the Life of Thomas Mifflin," in Historical Society of Pennsylvania, *Memoirs*, vol. ii (ib., 1830).

MIFFLIN, WARNER (1745-98). An American reformer, cousin of General Thomas Mifflin. He was born of Quaker parentage in Accomac Co., Va. While a mere boy he became impressed with the wrong of slavery, and about 1774 freed all his slaves and gave them compensation for past services. From that time forward he traveled about frequently to the various meetings of his sect, and did much to create a sentiment against slavery among his fellow Quakers. His religious principles led him to oppose the Revolutionary War, and at the request of the Yearly Meeting at Philadelphia he visited both Howe and Washington in order to point out the wickedness of the struggle. Mifflin is perhaps best remembered for having in November, 1792, presented to Congress a strong memorial against slavery which resulted in a spirited debate over the question of the right of petition. Consult Hilda Justice, *Life and Ancestry of Warner Mifflin* (Philadelphia, 1905).

MIGDOL. A place in Egypt mentioned in Ex. xiv. 2; Ezek. xxix. 10 (A. V. margin); Jer. xlv. 1 and xlv. 9. The name is identical with the Hebrew *migdal*, 'tower,' 'castle.' As an appellation it occurs in Egyptian inscriptions as early as the fourteenth century B.C. The exact location of the Migdol referred to in the story of the Exodus is uncertain. It may have been only a guardhouse on the road. A *Makthal* is spoken of in Papyrus Anastasi v. 20 as the "watchtower of Seti," but this place cannot be identified with certainty. From Ezek. xxix. 10 it is evident that a locality in the extreme north of Egypt is intended, as it is contrasted with Syene in the extreme south. In Jer. xlv. 1 it is mentioned in connection with Tahpanhea (Daphnæ) and Noph (Memphis), and in Jer. xlv. 9 as a place inhabited by exiled Jews. This may be identical with *Magdolo* in a Roman itinerary, possibly at the modern Tell el Her, 12 miles south of Pelusium.

MIGNARD, mé'nyár', PIERRE (1610-95). A French portrait and historical painter. He was born at Troyes, studied under Jean Boucher in Bourges and Simon Vouet in Paris, and resided for twenty-two years in Italy, where he was much influenced by the works of Annibale Carracci. At Rome he painted the portraits of Pope Alexander VII and many of the Roman nobility, and at Venice many Venetian nobles. In 1657 he was summoned by Louis XIV to Paris, where he painted the King ten times, Cardinal Mazarin, and many other celebrities. In 1664 he decorated the cupola of the church of Val-de-Grâce, Paris, where he represented a colossal Paradise, with two hundred figures, some of which are three times the size of life. This is the most ambitious fresco decoration in France, but the color has suffered much from time. He also painted decorations in the palace of Versailles. He was famous in Paris as the leader of the opposition against Le Brun and the Academy, but upon the latter's death in 1690 he fell heir to all his positions, becoming director of both the Gobelins and the Academy.

Mignard was the leading French portrait painter of the seventeenth century. His other pictures are rather cold, superficial, and conventional, but his coloring, derived from the Venetians, is good. The Louvre contains a number of his works, including the portrait of Madame de Maintenon, "The Virgin of the Grapes," "Saint Cecilia," and "Saint Luke Painting the Virgin." Others are in the galleries of Versailles, Madrid, St. Petersburg, Vienna, Berlin, London, and Florence. Consult Eugène Lebrun-Dalbanne, *Etude sur Pierre Mignard, sa vie, sa famille, et son œuvre* (Paris, 1878).

MIGNE, mé'ny', JACQUES PAUL (1800-75). A Roman Catholic editor. He was born in St. Flour, France, Oct. 25, 1800, and was educated at Orléans. In 1824 he became a priest and performed the functions of his office till 1833, when a pamphlet published by him, entitled *De la liberté, par un prêtre*, brought upon him the censure of the Bishop of Orléans, who forbade its publication. Migne went to Paris, and the same year established *L'Univers Religieux* (later called merely *L'Univers*), designed to harmonize the church with the free spirit of civil government. Later he commenced the publication of a collection of works called *Cours complets de théologie et d'écriture sainte*, and founded a publishing house on a large scale called *L'imprimerie catholique*, designed to furnish standard religious works at a low price. He established the daily *Vérité*, which in 1856 became the *Courrier de Paris*. The *Cours complets* finally grew into a very long series of volumes of standard authors under the general head of *Bibliothèque universelle du clergé et des laïques instruits*. The parts which are best known are *Patrologia Latina*, in 221 volumes (Paris, 1844-64); *Patrologia Græca* (Greek and Latin) in 165 volumes (Paris, 1857-66); and *Patrologia Græca* (in a Latin version), in 85 volumes (Paris, 1856-67). They are reprints of the famous Benedictine editions and many others, and, while not perfect, bring together very conveniently well-nigh the whole library of the ecclesiastical writers to Innocent III (d. 1216). His printing establishment suffered severely from fire in 1868, from the Franco-Prussian War in 1870, and from later ecclesiastical opposition. Migne died in Paris, Oct. 25, 1875.

MIGNET, mé'nyá', FRANÇOIS AUGUSTE MARIE (1796-1884). A French historian. He was born May 8, 1796, at Aix, in Provence, studied law in his native city with his lifelong friend, Adolphe Thiers, and in 1822 went to Paris in order to devote himself to a literary career. He found employment in writing for the public journals, and after giving lectures on modern history, which were received with great approbation, he wrote his *Histoire de la révolution française* (1824). In 1839 Mignet and Thiers in conjunction founded the liberal journal *Le National*. After the revolution of July he became a Councillor of State, and Keeper of the Archives of the Ministry of Foreign Affairs, but he lost these offices in 1848. In 1836 he was received into the French Academy. He edited *Négociations relatives à la succession d'Espagne sous Louis XIV* (1836-42). Other of his works are: *Notices et mémoires historiques* (1843-53, 1854); *Tw de Franklin* (1848); *Histoire de Marie Stuart* (1851); *Charles Quint, son abdication, son séjour et sa mort au monastère de Yuste* (10th ed., 1882); *Eloges historiques* (5th ed., 1884);

and *Rivalité de François I et de Charles V* (1872-75); also a drama entitled *Antonio Peres et Philippe II* (1845-46). Mignet died in Paris, March 24, 1884. Consult: Trefort, *Mignet und seine Werke* (Budapest, 1885); Simon, *Mignet, Michelet, Henri Martin* (Paris, 1889); Edouard Pet, *François Mignet* (ib., 1889); G. P. Gooch, "The Growth of Historical Science," in *Cambridge Modern History*, vol. xii (New York, 1910).

MIGNON, mé'nyon' (Fr., darling). 1. An Italian girl in love with Wilhelm, in Goethe's *Wilhelm Meisters Lehrjahre* (q.v.). 2. A derisive name applied to the effeminate favorites of Henry III of France. 3. An opera by Ambroise Thomas (q.v.), first produced in Paris, Nov. 17, 1866; in the United States, Nov. 22, 1871 (New York).

MIGNON, min-yóng', ABRAHAM (c.1640-79). A German painter, born in Frankfort-on-the-Main. He studied under Jacob Marrel, who took him to Haarlem, where he became the pupil of Jan David de Heem, the celebrated fruit and flower painter. He selected subjects similar to those his master painted, but never equaled him. His composition is more formal, his color less agreeable, and there is too much detail, although his better works are rich, warm, and harmonious. Among his more notable works are a study of flowers, fruit, and other objects, and some "Flowers in a Vase," in the Amsterdam Museum. The Van der Hoop collection in Amsterdam also has a dish with fruit, oysters, and bread, that is more broadly painted than is usual with him. Of his six pictures in the Louvre, two are very fine—a "Bouquet of Wild Flowers" and "Flowers and Fruit." He is also well represented by similar pieces in Dresden, Munich, Brussels, The Hague, Vienna, and other European cities.

MIGNONETTE, min'yün-ét' (Fr. *mignonette*, dim. of OF., Fr. *mignon*, favorite, dainty, from OHG. *minna*, Ger. *Minne*, love, Icel. *minna*, recollection; connected with Goth. *gamunan*, AS. *munan*, Icel. *muna*, to be mindful, Lat. *mens*, Gk. *ménos*, *menos*, mind, Skt. *man*, to think), *Reseda odorata*. An annual or perennial plant of the family Resedaceae, a native of the north of Africa, widely cultivated in gardens during summer and in greenhouses and windows during winter for its fragrant flowers. It has lanceolate entire or trifid leaves, and erect terminal racemes of small yellowish-white flowers, which have a six-parted calyx as long as the corolla, and three-toothed capsules. What is called tree mignonette is not even a distinct variety, but merely the common kind trained in an erect form, and prevented from early flowering by pinching off the ends of the shoots. White or upright mignonette (*Reseda alba*), a native of southern Europe, another very popular species, which grows from two to three feet high and bears its white flowers with brownish anthers in dense erect spikes, makes a fine border plant and grows well on ordinary garden soils. The seeds are sown in the open in April or May and later on the plants are thinned to a foot or 18 inches apart. Dyer's weed, or weld (*Reseda luteola*), is a tall species with long spikes of yellowish flowers. All species are generally propagated from seeds, but cuttings are sometimes used.

MIGRAINE, mi-grán' (OF., Fr. *migraine*, from Lat. *hemicranion*, from Gk. *ἡμικρανία*, *hémikrania*, pain in one side of the head, from *ἡμι*, *hēmi*, half + *κρανίον*, *kranion*, head), **MEGRIM**, **HEMICRANIA**, **SICK HEADACHE**. A paroxysmal

affection characterized by severe headache; usually one-sided and often associated with disorders of vision. The pain is more frequently left-sided, but the right half or the whole head may be affected. There is an hereditary element in many cases and the disease is apt to become established before the age of 30. Hemicrania has been recognized as a peculiar affection and attempts to explain its origin have continued from the earliest times to the present day. Aretæus and Galen associate it with diseases of the stomach and bile passages, and medical writers generally accepted this explanation up to the end of the Byzantine period. Tissot (in 1784) is credited with the first satisfactory description of the disease. He points out its hereditary character, the fact that the pain may be bilateral, and describes the associated phenomena. Tissot's description remained authoritative until 1873, when Liveing's monograph *On Megrin, Sick Headache, and Some Allied Disorders* appeared, although Vater, Heberden, Schönlein, Romberg, Du Bois Reymond, Claude Bernard, and many other distinguished investigators had also made observations upon the eye symptoms and nervous phenomena. At the present time several theories as to the etiology are put forward, all of which have a reasonable basis. These may be merely mentioned as follows: 1. The toxic hypothesis, which assumes that the irritation is due to poisons formed within the body, giving rise to irritation in the cranial nerves. These poisons have been variously assumed to be uric acid, xanthin, paraxanthin, etc. 2. The vasomotor theory assumes that the essential feature is a vasomotor spasm, followed by dilatation, causing anæmia and hyperæmia alternately, which acts on the nervous tissues and causes the headache. These two theories do not necessarily conflict. 3. The reflex hypothesis implicates the sensory nerves in different parts of the body, such as those supplying the eyes, ears, nose, throat, ovaries, and intestines. 4. Recently (1907) Spitzer advanced the theory that migraine is due to an hereditary or acquired anatomical defect resulting in complete or partial stenosis of the foramen of Monro. Whatever causes a passive or active hyperæmia of the brain in such individuals leads to hyperæmia of the choroid plexus with increased secretion of cerebro-spinal fluid and a more or less complete plugging of the foramen of Monro, followed by a rise of intracranial pressure due to distention of the lateral ventricle. The final result of this is an increase in intracranial tension with pressure on the branches of the fifth nerve supplying the dura mater. From all these theories a fairly correct understanding of the phenomena of migraine may be formed. The essential feature is increased intracranial pressure due to vasomotor changes. These may be brought about either by toxic, mechanical, or reflex influences. Women are the chief sufferers. Migraine is associated with gout, rheumatism, decayed teeth, eye strain, and uterine disorders. It is often due to reflex causes, such as powerful emotions, mental or bodily fatigue, disorders of digestion, and the like. The attacks may be unheralded, but generally there are premonitory symptoms of a widely different character in different individuals. Among these may be mentioned a sense of heaviness, with yawning, chilliness, dizziness, or depression, spasmodic closure of the eyelids, twitching, and various sensory disturbances,

ringing in the ears, irregularity in the taste and smell, and diminution of the saliva. These symptoms may be felt several minutes before the attack or may precede it by hours or several days. The speech may be disturbed, the phenomena being those of sensory aphasia. This, according to Charcot, is an intermittent aphasia, in which the patient can recall the right word at one moment but is unable to do so at the next. In some patients there is a transient loss of memory. Charcot attributes these disturbances to a vasomotor spasm near the speech centre. The headache may originate in the temple, forehead, eyeball, or occiput, whence it spreads gradually over one side of the head, sometimes extending to the neck or even to the arm. The face may be pale or congested and the eyes red; nausea or vomiting appears very early in the attack. Few affections are more prostrating than migraine. The attack endures for a variable time; the sufferer may be incapacitated for a few hours only or for a period of two or three days.

Treatment depends in large part upon the etiology, and is generally satisfactory. Exercise in the open air, moderate diet, hydrotherapy, and other measures tending to stabilize the blood pressure are demanded in most cases. Careful search is made for reflex factors in every part of the body, particularly those parts which are supplied by the fifth cranial nerve, since it is in branches of this nerve that the pain is localized. Ocular troubles, such as refractive errors and muscular imbalance, must be corrected. Points of pressure in the nose must be relieved and active or latent disease of the accessory nasal sinuses cured. The teeth must be thoroughly investigated and search made for cavities, diseased foci, or unerupted molars. An X-ray photograph will often reveal a diseased condition in the teeth or nasal cavities which may otherwise be unsuspected. In rare instances excessive auditory stimulation may bring on an attack. The persistent search for and correction of the above-mentioned peripheral or reflex factors has done far more to cure migraine than any other system of treatment devised. The medicinal treatment is merely symptomatic. The vast number of drugs which are mentioned in this connection attest the inefficiency of this plan of treatment. Among the pain relievers are antipyrine, cannabis indica, and chloroform; nitroglycerin and ergot are used to equalize the circulation, and iron, arsenic, nux vomica, etc., may be given as tonics. Electricity and massage are often helpful. During the paroxysm the sufferer should remain quiet in bed and in a dark room. There is an extensive literature in connection with the subject, most of it German. Consult: Edward Liveing, *On Migrain, Sick Headache, and Some Allied Disorders* (London, 1873); Alexander Spitzer, *Ueber Migräne* (Jena, 1901); George Flatau, *Die Migräne* (Berlin, 1912); Auerbach, *Headache*, translated by Playfair (London, 1913). See HEADACHE.

MIGRATION (Lat. *migratio*, from *migrare*, to migrate). The movement of peoples from one place to another, usually, though not necessarily, for the purpose of settlement. Movements of population were no doubt common in prehistoric times, and in the historic period there have been notable migrations that have affected the history of civilization. Students of African ethnology have traced migrations among the

negro tribes of that continent that are of importance to the ethnographer; and a more complete knowledge of the ethnology and prehistoric archaeology of America will probably make it possible to trace such movements among the American tribes, and perhaps will throw some light upon their origin. Migration has played a large part in theories for the explanation of cultural transmission, but W. H. R. Rivers has recently suggested that cultural traits may be diffused by relatively small groups of wandering immigrants, provided their culture succeeds in profoundly impressing the people with whom they come into contact.

Aryan. The accepted hypothesis until recently was that the so-called Aryan or Indo-European family—embracing the Celtic, Teutonic, Greek, Latin, Balto-Slavonic, Armenian, and Indo-Iranian peoples—originated in the Pamirian region of Central Asia, whence the last-named group moved into India and the Iranian Plateau, while the remaining groups migrated westward, the Celtic peoples leading the way and advancing to central Europe, the Teutons settling about the Baltic, the Greeks and Latins finding their way to the Mediterranean, the Balto-Slavonic to the Baltic Provinces, Lithuania, and the region of steppes and rivers to the southeast, while the Armenians settled near the Caspian Sea. Later investigation of the remains of primitive man in Europe, together with a comparative study of the Aryan tongues, has cast grave doubt upon this theory, and made it seem probable that there never was an undivided Aryan family, unless the term be restricted to the peoples of northern India and Persia, and that the European Aryan groups originated near their present habitats; that the Baltic was the original centre of diffusion of European races, and that the Græco-Latins migrated southward to the Mediterranean and the Indo-Iranians and Armenians southeast into Asia. Another hypothesis locates the original Aryan home in the steppes of southeastern Europe. (See ARYAN; INDO-GERMANIC LANGUAGES.) In prehistoric times the Celtic peoples spread over much of Europe and even into Asia Minor in great migrations. From them the Teutonic tribes acquired much of their civilization. See CELTIC PEOPLES.

German. The migrations of whole Teutonic tribes, during the years of decline of the Roman Empire, had a profound influence upon the social and political development of Europe, and are known preëminently as the migrations (*Völkerwanderung*). These peoples had been on migrations, intermittently, for centuries before the time when Tacitus wrote his *Germania*. In the centuries following the period when he gave his account of them they were engaged in intertribal strife, which resulted in the loss of identity of the weaker tribes, the remnants of which were merged in the new confederacies—Goths, Vandals, Alemanni, Franks, and Burgundians (q.v.). In the fourth century A.D. the Goths were spread over the country north of the Danube. There came upon them from Asia a great migratory wave of the nomadic Huns (q.v.), a Mongolian people. The Goths (q.v.) were unable to resist this inroad, the Ostrogoths were enslaved by the Huns, but the Visigoths obtained permission from the Roman Emperor to cross the Danube into Roman territory. Because of ill treatment by the Romans they revolted and in the battle of Adrianople (378 A.D.)

annihilated a Roman army and killed the Emperor. But they made peace with the new Emperor, Theodosius, and until his death, in 395 A.D., remained quiet. Then they started on their great migration under Alaric (q.v.), which resulted in the establishment of the Visigothic kingdom in southern Gaul and Spain. This march of the Visigoths was the beginning of "the migrations," and it was soon followed by movements of other Germanic tribes. The Vandals (q.v.), who in the fourth century were settled between the Danube and the Theiss, in 401 A.D. started on their long migration which traversed part of Gaul and Spain and finally led to the establishment of their kingdom in north Africa. The Burgundians (q.v.), who at an early date had migrated from their home between the rivers Oder and Vistula, invaded Gaul early in the fifth century and established a kingdom on the Rhine. After defeats by both the Romans and the Huns the small remnant settled in what is now Savoy. The Ostrogoths (see GOTHS), who were living north of the Black Sea, escaped from servitude to the Huns about the middle of the fifth century. Under Theodoric the Great (q.v.) they invaded Italy, nominally as soldiers of the Emperor, and established there the Ostrogothic kingdom, in 493, after the murder of Odoacer (q.v.). The last great German migration into Italy was made by the Lombards. At the beginning of the Christian era their home was on the left bank of the lower Elbe. Little is known of their wanderings until they reached the Danube about 487 A.D. In 568, under the leadership of Alboin (q.v.), they and their allies, including 20,000 Saxons, crossed the Alps and soon conquered northern Italy, Lombardy. Under "the dukes" they spread over almost the whole of Italy. In the meantime the Franks (q.v.) had gradually extended their conquests and migrations southward. Under Clovis (q.v.) they obtained possession of almost all Gaul. The Angles, Saxons, and Jutes (qq.v.), probably from Schleswig and the neighboring lands, invaded Britain from about 449 to 549 A.D.

The above were the most important of the German migrations. The numbers involved in them were considerable, but not so great as was formerly supposed; no accurate estimate can be given. These migrations show the depopulation of some portions of the Roman Empire, as whole tribes of barbarians found homes without exterminating or driving out the inhabitants. They also show the weakness of the Empire, which was powerless to check these bands encumbered by their women and children and all their property. In the sixth century Justinian (q.v.) reconquered Africa from the Vandals and Italy from the Ostrogoths; the Franks conquered the Burgundians and the Visigoths in Gaul. In the eighth century the Mohammedans conquered the Visigoths in Spain and the Franks subdued most of the Lombards in Italy.

Asiatic. The migrations of the Asiatic peoples are very different from the Teutonic, because they did not carry their households with them. From time immemorial the weaker tribes in the steppes of Central Asia have been driven out from their pastures and robbed of their wives by the stronger, and consequently have been compelled to seek homes elsewhere. While weaker than their conquerors they have been almost invincible to the settled peoples, whose lands they harried by sudden invasions on horse-

back. When they found a competent leader they made widely extended conquests, enslaving the people and taking their women from them. On the death of the leader the unification frequently ceased and the tribe lost its power. Of this character were all the great invasions of Europe by the nomads, Scythians, Sarmatians, Huns, Bulgars, Avars, Magyars (qq.v.), and Cumans. Of these invasions that of the Huns, in the fourth century, was probably the most influential for European history, as it forced into feverish activity the German migrations. Under Attila (q.v.), in the first half of the fifth century, the Huns built up a strong power in central Europe, but this went to pieces after Attila's death. In the later Middle Ages the movements begun by Genghis Khan (q.v.) had a great effect upon all eastern Europe. Consult: Bryce, "Migrations of the Races of Men Considered Historically," in *Smithsonian Institution, Annual Report, 1893* (Washington, 1894); E. A. Freeman, *Western Europe in the Fifth Century* (New York, 1904); J. A. G. von Pflugk-Harttung, *Great Migrations* (Philadelphia, 1905); A. C. Haddon, *The Wanderings of Peoples* (Cambridge, 1912). See MONGOL DYNASTIES; TIMUR; TURKEY, section *Ethnology*.

The migrations in modern times have been on a larger scale than in the past, and are discussed in the article upon EMIGRATION. For the effects of the Germanic migrations, see EUROPE, section on *History*. For bibliography, see the articles on the various nations and tribes mentioned.

MIGRATION, WAGNER'S LAW OF. In evolution, one of the main agencies leading to the isolation of animals, and consequently to the formation of local races, varieties, and species. This was first pointed out by Moritz Wagner in 1868. He stated his views in three general propositions: (1) the greater the change in the conditions to which individuals are subjected on emigrating to another territory, the more intense must be the inherent individual variability of each organism; (2) the less the even tenor of this increased individual variability of organisms is interrupted by frequent crosses with emigrants of the old stock, the more frequently will nature be successful in forming a new variety or incipient species by the accumulation and inheritance of fresh characteristics; (3) the more advantageous to the variety the change in each single organ, the better it will be able to adapt itself to surrounding circumstances; and the longer the selection of an incipient variety of colonists remains undisturbed by the old stock, the more frequently will a new species arise out of the variety. These laws are fully illustrated by Wagner in his works, and by later observers. Wagner claimed that evolution by natural selection is impossible unless it be assisted by geographical isolation in order to prevent the swamping effects of intercrossing. The numerous facts observed by Wagner and others show that some of the barriers isolating incipient species are broad rapid rivers, oceans, and mountains. He speaks of the extraordinary phenomena of so many species of plants and animals peculiar to the volcanoes and isolated mountains of Quito. "Without the distribution of organisms by migration in connection with local selection it would be inexplicable. The gigantic isolated mountains of this highland act a similar part in the formation of varieties and species as the islands of the archipelago, for instance, of the Galapagos." Wagner also

claimed that adaptation to changed conditions of life and transformation appear to be tantamount to a renovation. Species, he said, which did not migrate, and consequently did not alter in form, became extinct. Consult Moritz Wagner, *The Darwinian Theory and the Law of the Migration of Organisms* (Munich, 1868; trans. by Laird, London, 1873).

MIGRATION OF ANIMALS. The word migration is used in two senses: either to refer to those periodical changes of location such as are made by many species of birds and fishes, by some mammals, and by a few insects, or to those irregular dispersions caused by overcrowding and lack of food or water.

Mammals. Among mammals migrations in the first sense are mainly confined to certain Cetacea, which regularly move from and to the polar seas with the alternating seasons. Regular seasonal movements, truly migratory but short, are practiced by many land animals, especially the herbivores. All deer, goats, sheep, antelopes, and the like, which dwell in mountainous regions, regularly ascend the heights in early summer to get the new grass, find safer solitudes, escape the lowland flies, and otherwise better themselves. In the fall they come down as the snow and cold increase upon the heights, and seek the valleys or the neighboring plains. The American bison formerly was wont to retreat from the mountains to the plains during severe winters, while those on the northerly plains tended to move south. Before the time of railroads the great body of the pronghorns of the plains used to migrate from the northern area of their range to the milder regions south of the Platte River, and returned north in the spring. Still more striking is the regular and prolonged annual migration of the caribou from the Arctic shores of America to the southerly interior, especially in the region north and east of Hudson Bay; they cannot live so far north during the winter, but go back as soon as the snow melts in spring. In all these cases there is an accompanying migration of certain large predacious animals, such as wolves, which depend upon the grazers for food. Similar facts may be cited from the plain regions of Asia, Australia, Patagonia, the Sahara, and South Africa, where seasonal changes, either of cold or drought or the parching of pasturage, compel annual migrations to and from other regions not far distant. It will be seen that these movements are under compulsion of the lack of food (or frequently in desert regions of water), and are continued only when and so far as necessary. Mammals are too slow and hampered in their movements on land to make long, rapid journeys, such as a bird or fish is able to accomplish through the unobstructed air or water; and most mammals either can find food all the year round, or have acquired the power, by storage of provisions or by sinking into dormancy, of tiding over the seasons of scarcity.

Overflows of Mammalian Life. Mammals, including man, take part in certain much more rare but more universal and permanent removals. The most conspicuous instance is afforded by the lemmings of central Norway and Sweden, which at uncertain intervals come down in vast hordes into the lowlands, as is fully described under **LEMMING**. They travel by night, feed and multiply excessively, and in from one to three years the few which escape the hordes of enemies following them reach the Atlantic or the Gulf

of Bothnia. It is believed that these sudden incursions are the dispersal of an overpopulation in the ordinary habitat of the species, due to a combination of favoring circumstances causing an increase of a naturally fecund race until the country cannot longer support the numbers. The animals are started abroad by famine, and continue the flight in aimless restlessness until an equilibrium is restored. The same thing happens occasionally with various other small rodents. "Plagues" of mice have broken out frequently in the grain-growing regions of southern Russia and in other parts of the world. In the western part of the United States, until hunting kept down the stock, there used to be irregular but prodigious movements of squirrels (normally extremely numerous there), which would appear in droves over a wide range of country, all traveling steadily in one direction, until they gradually vanished. The writings of Audubon, Godman, and other early naturalists contain many records of these movements, which did not cease until about 1840. The theoretic and historic incursions of human hosts from Asia into Europe, the spread of the Bantu races which overran Africa, and similar "waves" or "migrations" of conquering men, fall into the same category, but their superior adaptability has enabled them, or some of them, to remain and possess the land.

Insects. The insects afford many cases of mass movements similar to those of mammals, and also a rare approach to true migrations. The swarms of grasshoppers, or locusts, which occasionally visit parts of Africa and Asia, are one of the most familiar phenomena of those regions; and they are accompanied by a rapacious following of birds and mammals feeding upon the traveling hosts of insects, which disperse, dwindle, and finally disappear. In the United States the most disastrous excursions of these insects have been from the Rocky Mountains eastward. They are of irregular occurrence, and the returning swarm the succeeding year is composed only of the descendants of the original emigrants—a fact which contains a hint as to the possible origin of the true migratory habit in others. Irregular movements without, so far as we know, any attempt to return to the original home are illustrated by the army worm, chinch bug (q.v.), and cotton worm. (See **COTTON INSECTS**.) These migrations are due to overcrowding and lack of food. There are still slower migrations among insects, which may be termed "spreading." Thus the Colorado potato beetle, a native of the Rocky Mountain plateau, spread eastward, when suitable food was offered it by the cultivation of potatoes, until it now occurs all over the potato region of eastern North America, and, like the brown rat, it permanently occupies all the new territory it enters. A few insects (butterflies) are known to migrate in the sense that fish and birds do.

Reptiles and Fishes. Such phenomena are entirely unknown among reptiles, for obvious reasons, with the possible exception of sea-going turtles, which may withdraw into deeper water or more southerly latitudes in winter than in summer. Many fishes perform long and complex wanderings, but how they are guided in some cases across and up and down the ocean will be a very difficult problem to solve. Salmon and other anadromes come from the sea each spring and ascend hundreds of miles up rivers so as to spawn in places suited to the needs of

the young. The fish so bred return to spawn in the water of their birth, as has been demonstrated by marking smelt that have been transplanted and hatched in rivers previously unoccupied by them; the marked smelt returned from the sea to spawn in the river of their adoption. Experiments upon herring along the Massachusetts coast confirm this conclusion. Sea fishes generally retire to comparatively deep water, and probably many species go southward in winter, while in summer they spread northward and approach the shores, river mouths, or other spawning places. These migrations are induced by reproductive desires and necessities, and the slight variation in the time of the coming of each species, which fishermen expect with fair regularity, seems due to variations in the temperature of the water. It is probable that even these ocean wanderers return to the same part of the coast where they were bred, and that in some cases, as of the Atlantic salmon, exaggerated notions have prevailed as to the distance to which they go in winter. See SALMON.

The Migration of Birds. More conspicuous and interesting, and quite as difficult to explain, are the migrations of the birds, which have been the theme of poetry, homily, and fable, as well as a baffling subject of inquiry, ever since men began to notice the ways of animals.

Most persons have a vague idea that the habit of yearly migration among birds is uniform and universal, but this is not so. Most birds do not migrate at all, and among those that do great diversity exists, so great that the custom seems almost an individual rather than a racial one. The whole body of ratite birds—ostriches, rheas, cassowaries, and the like—are nonmigratory. The fish-eating sea fowl make no more of an annual migration than is necessary to escape from the ice and darkness of their most polar haunts to where there may be open sea. These are wanderers rather than migrants. Gulls and terns, geese, ducks, and the wading marsh and beach birds are in the main migratory, and include some of the most remarkable examples. Of the game birds fewer are real migrants, but here again a few notable exceptions exist, of which one of the most familiar is that of the common European quail, which has been taken so numerous for centuries on both sides of the Mediterranean, and whose migratory flocks still feed travelers wandering in the wilderness of Sinai. The pigeon tribe is sedentary as a rule, also, yet one of its species—the passenger pigeon of North America—has become the very type and exemplar of a migratory bird. Many, but not all, birds of prey regularly migrate, but it is a question whether they do not, in most cases, accompany the movements of the smaller birds rather than travel of their own impulse. Parrots are almost wholly nonmigratory. It is not, then, until we have passed 21 of the 23 classified orders of birds (with the exceptions above noted) that we come to those groups, the picarian and passerine birds, in which the custom of seasonal migration is a prominent characteristic. These are, to be sure, the most numerous as well as the most highly organized orders; yet a large number even here do not migrate at all from temperate regions, but form a resident or partially migrant population in all moderate latitudes, where they remain all the year round. On the whole, the large majority of the total list of the birds of the world are not migratory to any considerable degree.

When we examine the minority which does annually alternate between southerly winter and northerly summer residences many curious facts are discernible. First, it is noticeable that all migratory birds belong to the colder latitudes of the globe; and, on the other hand, that those groups which are wholly nonmigratory represent the primitive types—birds whose ancestry goes back to times when a comparatively warm climate prevailed over the now unbearably cold and sterile polar regions. In general, two-thirds of the birds of the middle temperate zones, both north and south, are migrants, and the total is a very small part of the entire avifauna of the world. Taking up the character of the migratory birds as a class, it appears, first, that they are such as either subsist wholly or mainly on soft-bodied insects—larvæ, worms, and the like—or give their young such fare; second, such as gain their living from fresh or brackish waters or mud, which is likely to freeze; and third, such as follow small birds in order to prey upon them. It is also significantly true that they represent families whose mass and affiliations are found in the tropics, in many cases only one or two species being known elsewhere. Europe's single cuckoo, the eastern North American humming bird, tanagers, orioles, and the like, are familiar and striking examples of this fact. On the other hand, the nonmigratory or resident birds of the temperate zones belong to families mainly distributed outside the tropics and separable, broadly speaking, on other grounds. This state of things points to the explanation that the extratropical parts of the world, depopulated of birds by the cold, ice, and excessive rains of the Pleistocene or Glacial period, were restocked from the crowded intertropical preserves as fast as the amelioration of the climate permitted plants and animals to occupy the temperate and subarctic regions; and that the reactive effect of the new country steadily checked colonization by selecting only those species adapted or adaptive to the new conditions. In this light the seasonal migration of birds must be viewed as an annual excursion, constantly repeated by certain species that have the habit (and not by others), outward from equatorial regions to a greater or less distance poleward.

Beginning of the Seasonal Movement. As the close of the rainy season approaches in the tropics migratory strangers gradually separate themselves from the resident birds, now beginning domestic cares, and disappear. What starts them off just as the rains are bringing an increase of both plant and insect food we do not know. Their ovaries show little preparatory enlargement, and few or none are mated. As they slowly proceed, keeping pace with the lifting sun and the opening spring, they will gradually concentrate upon certain highways, or "migration routes." The old males take the lead, probably merely through superior strength of wing; and it is not until the bulk of these have passed by that the females appear, followed, after an interval, by yearling birds.

The weather encountered, always uncertain, influences this progress decidedly, warm southerly winds encouraging the birds to go forward, while cold spells or northerly storms check them, sometimes for a fortnight or more, and occasionally destroy large numbers. When sunshine and southerly breezes again prevail the accumulated host goes forward in what observers call a "wave" of migration. Such checks are local;

and larger influences have an effect, so that the movement is uniformly earlier in some parts of the continent than in others.

Migration Routes. It is also true that the movement is not uniformly distributed. On the contrary, there are certain definite routes or paths which birds follow in especially great numbers. The greater of these routes, or "fly lines," are generally recognized and seem to be determined partly by topography, but to a greater degree by considerations of security and subsistence. The most thickly frequented routes are along ocean coasts, river valleys, or mountain ranges. European specialists, like Palmen and Middendorf, have outlined several such "fly lines" with great particularity, and when sketched upon a map they are seen to coincide in a general way with the valley system of that continent. Similar highways are traceable in North America. One runs along the Pacific coast and another up the valley of the Rio Grande and along the connected valleys and parks between the parallel ranges of the Rocky Mountains. East of the plains a horde of spring birds enters the United States along the eastern lowlands of Mexico and by way of the West Indies, and soon divides into definite streams of travel. Parted first by the southern extremity of the Alleghenies into two main currents, one goes to the right up the Atlantic coast and through the Hudson Valley and New England, while a second, to the left, ascends the Mississippi, Missouri, and Ohio, diverging more and more up tributary valleys, until all the central and northern parts of the continent are supplied. A little reflection will show how likely, from the nature of the case, are these routes. They are natural bird roads, without obstacles, and they afford easy guidance, plentiful vegetation, and consequent protection against enemies and storms, and the abundance of insect food belonging to watercourses.

Nocturnal and High-Flying Migrants. A large part of the migration of many birds is made at night, especially the natural night fliers, like owls and goatsuckers and the great body of small, timid birds that in their daily life seek concealment and obtain their food in shady, secluded places. It is only the day goes that we ordinarily see migrating, and these more commonly in spring than in fall; but every observer has noted how after a favorable night the woods will be full of birds at dawn where none were to be seen the evening before. English and American ornithologists, led by Baird about 1875, have collected at lighthouses and other watching places systematic data in respect to night migration.

Guidance. What guides these travelers on their annual journeys across continents and over seas? This has been an eager question ever since men began to watch the ways of the birds. If anything approaching a rule has been disclosed it is that diversity prevails rather than uniformity. Birds closely allied in structure, diet, nesting habits, and so forth, vary immensely in the extent and manner of their migrations. While some travel twice a year from the equator to near the poles, others of the same family, or genus even, never leave warm latitudes at all. The increasing perception of this individuality in animals inclines one more and more to believe that migratory birds are guided in the majority of cases by the teaching of their elders, and by their own observation and mem-

ory, rather than by any extraordinary faculties or process. Brewster declares that the manner of migration of birds is determined by one, two, or all of the following considerations, viz.: (1) habitual manner of procuring food; (2) disposition; (3) wing power. Much evidence exists in favor of this simple and practical explanation, but unfortunately contrary and unexplained facts still confront us. European ornithologists assert that there the young of many species precede the adults on their journey southward in the autumn. Cooke and Widman, in their elaborate *Report on Bird Migration in the Mississippi Valley*, say the same for the interior of North America. On the other hand, William Brewster, who has observed this matter with the highest zeal and intelligence, maintains the opposite view as the result of long experience in New England and eastern Canada, and declares that the young never precede older birds in the fall, explaining that the first southward flights of adult birds have been overlooked because they were unexpectedly early. He has elucidated this with much detail in the *Memoirs* (No. 1) of the *Nuttall Ornithological Club*.

That this is the true history of migration in respect to many and various kinds of birds cannot be gainsaid; that it is an all-sufficient explanation is not universally admitted. The powers of recognition and recollection involved are doubted by some; yet all animals are strong in this direction—perhaps no mental faculties are so distinctly manifested by brutes as observation and memory. Examples might be drawn from every class, but homing pigeons are most closely to the point. There can be no reason to suppose other birds are less able in this respect until we have taken pains to exploit their abilities. No mysterious "homing faculty" need be summoned. The great height at which pigeons usually fly enables them to survey a wide extent of country and find some points with which they have been previously familiarized; from this a second is visible, and so on, leading the pigeon straight home as the pioneer follows a blazed trail through a forest. Wild birds may be supposed to do the same, and their wish to get a very wide view of the landscape explains the height to which they rise in these journeys and their descent and confusion in murky weather. From a height of 10,000 feet both shores of the Mediterranean, e.g., would probably be visible to a bird's eye, at any rate in the narrower places where they mostly cross. It must be confessed, however, that this explanation does not cover the case of those birds which migrate across ocean spaces of one or two thousand miles. Here it seems necessary to believe that they are guided by an intuitive sense of direction—a feeling for the points of the compass, so to speak. Something so closely akin to this instinctive power of orientation is observable among other animals, including the human savage, that it may be very well conceded to the birds. The placing of small, marked metal bands on the legs of young birds has recently been carried on extensively both in the United States and Europe, and has already begun to yield valuable, definite results in indicating the general movements of individual birds.

Bibliography. For references to early essays, and to many essays and books in European languages, consult Newton, article "Migration," in *Dictionary of Birds* (New York, 1893-96), and Giebel, *Thesaurus Ornithologiae* (Leipzig, 1873-

77); also S. Berthelot, *Oiseaux voyageurs et poissons de passage: étude comparée d'organisme de mœurs et d'instinct* (2 vols., Paris, 1875-76); W. W. Cooke, *Report on Bird Migration in the Mississippi Valley* (Washington, 1888); Palmén, translation by Shoemaker of a report to the International Ornithological Congress at Budapest, 1891, in *Report of the Smithsonian Institution for 1892* (ib., 1893); Gätke, *Die Vogelwarte Helgoland* (Brunswick, 1891), translated by Rosenstock as *Helgoland as an Ornithological Observatory* (Edinburgh, 1895); Whitlock, *The Migration of Birds: A Consideration of Herr Gätke's Views* (London, 1897). This combats many of Gätke's statements and theories. See also C. Dixon, *The Migration of Birds: An Attempt to Reduce Avian Season Flight to Law* (amended edition, London, 1897), an ambitious book of theory, not well sustained; W. E. Clarke, *Studies in Bird Migration* (2 vols., ib., 1912); T. A. Coward, *Migration of Birds* (Cambridge, 1912), containing a bibliography; E. Trouessart, "L'influence de la guerre sur la faune du pays et les migrations des oiseaux," in *La Natur*, vol. xliii (Paris, 1915). H. Scudder, *Butterflies of the Eastern United States and Canada* (Boston, 1889); F. E. Beddard, *Book of Whales* (New York, 1900); J. A. Thomson, *The Wonder of Life* (ib., 1914).

MIGRATION OF PLANTS. The natural movement of plants from one area to another. This term is thus somewhat in contrast to naturalization (q.v.). Migration of species is possible by reason of variations in the structural adaptations which are found in most plants. Among these perhaps the most important are the structures which are concerned in the dispersal of seeds and spores, which may be scattered by means of birds, wind, or water to very great distances. Besides these methods of dispersal, certain plants may be scattered in a vegetative way for great distances and become established far from the original home. Thus, the common water weed *Elodea* is believed to have spread all over Europe vegetatively from a single plant introduced in the early part of the nineteenth century. It seems likely that after a time a certain equilibrium between the various species of the world will have been reached and that each particular species will be found in the conditions best suited to it. When this time comes further migration would seem to be without result, whether the scattering of seeds takes place or not. It must be remembered, however, that various factors enter in to disturb any equilibrium which may be formed. In the first place, there are changes in the organic world itself; i.e., new species of both plants and animals are developed from time to time through evolution and new disturbances in the so-called equilibrium must arise. In the second place, the external world suffers tremendous changes. It is probably this last cause which has been most responsible for the migration of plants. Through the geological ages continents have arisen and passed away, and all these changes must have been accompanied by changes in the mutual relations of the species then living. Changes in climate have taken place many times in the world's history, and all of these changes must have been attended with great plant migrations.

To illustrate: the oncoming of the ice epoch caused a southern movement of the climatic zones, and the species which had become adapted to a particular climate moved south to a greater or less degree *pari passu* with the climatic movement. Postglacial times have witnessed northern migrations, which are necessarily much slower than the northern migrations of the southern zones. Plants must not be regarded as less active migrants than animals, though they make no seasonal migrations.

MIGUEL, mé-gál', DOM MIGUEL MARIA EVARISTO DE BRAGAÇA (1802-66). An aspirant for the Portuguese throne, the third son of John VI of Portugal. He was brought up in Brazil, whither his parents had fled in 1807, and returned to Portugal in 1821 with very little education, a debauchee and a superstitious bigot. He put himself at the head of the reactionary party and plotted the overthrow of his father and of constitutional government. In 1824 he caused his father to be closely guarded, arrested the ministers, and sought to overthrow the government, but failed and was sent into banishment. In 1826 his brother Dom Pedro, Emperor of Brazil, succeeded to the throne. He relinquished the crown of Portugal to his young daughter, Dona Maria da Gloria, and betrothed her to her uncle Miguel, who was made regent. Dom Miguel in 1828 usurped the throne, abolished the constitution, and introduced a reign of terror. Dom Pedro, who had been forced to abdicate the throne of Brazil in 1831, placed himself in 1832 at the head of an expeditionary force, which had been collected by the opponents of Dom Miguel, and proceeded to dethrone the usurper. He entered Oporto in July, and a year later, after the defeat of Dom Miguel's fleet, was in possession of Lisbon. Spain recognized Maria as the legitimate sovereign. England and France followed suit, and Dom Miguel was forced to give up all claims to the crown (1834). He died at Brombach in Baden. To the common estimate of Dom Miguel's character exception is taken by Cardinal Hergenröther in the *Handbuch der allgemeinen Kirchengeschichte*, vol. iii, p. 847 ff., (3d ed., 1886), where he is said to be a noble prince, possessing the affection of his subjects.

MIHRAB, mé-ráb'. See KIBLAH; MOSQUE.

MIJATOVICH, mé-yá'tó-vèch, CHEDOMILLE (1842-). A Servian diplomat and author. He was born in Belgrade; studied at Munich, Leipzig, and Zurich; taught economics at Belgrade (1866); and was general secretary in the Servian Ministry of Finance from 1869 to 1871 and Minister of this department in 1873-75 and of Foreign Affairs as well as Finance in 1880. About 1874 he broke with Ristić, in whose cabinet he had served, and joined the Progressive party. From 1875 on he was a Senator of the Kingdom of Servia. In 1886 he represented Servia in making peace with Bulgaria; in 1894 was Minister of Finance again and Ambassador to Rumania; in 1899 was delegate to The Hague Peace Conference; and in 1895-1900 and (after serving at Constantinople) in 1902-03 was Minister from Servia at the Court of St. James's, resigning after the assassination of King Alexander, which he described in *A Royal Tragedy* (1906). He wrote *Servia and the Servians* (1908), *Servia of the Servians* (1913), and, in Servian, several volumes of history, economics, and fiction. His English wife, Elodie Lawton (died 1908), wrote a *History of Modern Servia* (1872) and *Servian Folk Lore* (1874).

MIKADO, mē-kā'dō (Jap., Exalted Gate). Formerly the popular and official title of the Emperor of Japan, occurring in poetry and history throughout the whole range of Japanese literature. Though comparatively obsolete in the Japan of the twentieth century, the word has found a fixed and honored place in the English language. The Mikado dynasty is probably the oldest in the world, Yoshihito (q.v.) being reckoned by most authors the one hundred twenty-second of the Imperial line, the first being Jimmu Tenno, who in the official chronology began to reign 660 B.C. Descent is claimed from the gods that created heaven and earth. The origin of the line is lost in mythology, and there is little or no historical foundation for it before the fourth century. The first 17 mikados (660 B.C.—399 A.D.) are said to have died at ages ranging from 100 to 141 years. The average reign in the whole line is 20 years. Each mikado has a personal name, but no family name, nor is the name of the mikado ever repeated. Each has also a posthumous title, by which he is known in history. Seven of the mikados were women. See **MIJI TENNO**.

MIKADO, THE. A comic opera by William S. Gilbert and Sir Arthur S. Sullivan (qq.v.), first produced in London, March 14, 1885; in the United States, Aug. 19, 1885 (New York).

MIKAL. See **LEBENSOMN**, **MICAH JOSEPH**.

MIKANIA (Neo-Lat., named in honor of J. C. Mikan, a Bohemian botanist of the nineteenth century). A genus of plants of the family Compositæ, nearly allied to *Eupatorium* (q.v.). *Mikania officinalis* is a Brazilian species, with erect stem and heart-shaped leaves, abounding in a bitter principle and an aromatic oil, reputed useful in medicine. *Mikania amara* and *Mikania cordifolia* (twining herbs), also natives of the warm parts of South America, are among the plants which have acquired a high reputation—deserved or undeserved—for the cure of snake bites. The former is remarkable for the large indigo-blue spots on the underside of its ovate leaves. *Mikania scandens*, sometimes called climbing hempweed, is a native of the United States, growing in moist soils from New England to Texas.

MIKHAILOFF-SHELLER, mē'ka-yil'of-shel'ler, ALEXANDER. See **SHELLER**, ALEXANDER KONSTANTINOVITCH.

MIKHAILOV, mē-ka-yil'of, MIKHAIL LARIONOVITCH (1826-65). A Russian journalist and novelist, born in the Ural Mountains. He was educated in St. Petersburg and began his literary work with translations, chiefly from Heine. These were collected in one volume (1858), and his articles for the *Sovremennik* (*Contemporary*) and other periodicals, as well as his stories, notably *Adam Adamovitch* (1851), were published in two volumes in 1859. He shared the dreams of the revolutionists of his own country and was exiled to Siberia, where he died.

MIKHAILOVSKI, mē'ka-yil'of'ské, NIKOLAI KONSTANTINOVITCH (1842-1904). A Russian essayist, critic, and sociologist. He translated one of Proudhon's works into Russian, but it was his critical work on the famous *Annals of the Fatherland* (*Otčestvennyia Zapiski*), with which he was connected from 1869 to its suppression in 1884, that made him famous. For it he wrote literary notes regularly, beginning in 1872, and many papers, on truth, heroes, and the crowd, Darwinism, Socialism, positivism, and the systems of Spencer and Mill. In 1873

he became one of the editors of the *Northern Messenger* (*Sévernoi Véstnik*), and from 1880 to his death he edited the *Russkoe Bogatstvo* (*Russian Wealth*). Mikhailovski's best-known monograph is on *The True Nature of Progress* (trans. into French by Louis, *Qu'est-ce que le progrès?* 1879). Mikhailovski rejects the organic conception of society and holds that social processes are not wholly reducible to biological or intellectual terms. Social progress, in his view, presupposes social justice—the proper division of labor—and is brought about through the conscious and sympathetic coöperation of the individuals striving to realize their full measure of individuality. The end of progress is the identity of truth and justice (Russ., *pravda*). Mikhailovski also wrote several literary studies, notably on Tolstoy (1887) and Shtchedrin (1890). His papers have been collected several times, the latest edition of his *Works* being prepared by Kolosov (St. Petersburg, 1913).

MIKHAILOVSKI-DANILEVSKI, mē'ka-yil'of'ské dā'nē-lyef'ské, ALEXANDER IVANOVITCH (1790-1848). A Russian soldier and historian. He took part in the war with France (1812-13) as Kutusoff's aid-de-camp and was head chancellor of Wolkonski in 1813-14. In the war with Turkey (1829) he served as major general, was promoted to be lieutenant general in 1835, and became a member of the war council and Senator in 1839. He wrote a *History of the Turkish War of 1806-12* (1843), besides accounts of his experiences in the campaigns of 1812-13 (1834) and of 1814-15 (1849-50). His collected works were published (1849-50) in seven volumes. They are marked by a freedom of style and a patriotic sentiment that sometimes verged into inaccuracies.

MIKKELSEN, mik'kel-sén, AKSEL (1849-). A Danish educator, born at Hjörning, the introducer and organizer of sloyd schools in Denmark. In 1872-83 he operated a machine shop, later he organized sloyd schools, finally the Sloyd Seminary in Copenhagen, and in 1907 he was appointed sloyd inspector for Denmark. Through his energetic work as teacher, author, and lecturer he greatly developed this form of education throughout the country. Among his many writings on the subject are: *Hvad er Sløid?* (What is Sloyd?) (1886); *Hvordan arbejder Sløidkolen?* (How Does the Sloyd School Work?) (1886); *Sløidlarer* (Instruction in Sloyd) (1894); *Arbejdstillinger* (Positions when Working) (1896).

MIKKELSEN, EJNAR (1880-). A Danish explorer, born at Vester Brønderslev, Jutland, who served in the Amstrup expedition to Christian XI Land, East Greenland (1900), and in the Baldwin-Ziegler expedition to Franz Josef Land (1900-02). With Leflingwell he organized the Anglo-American polar expedition which wintered at Flaxman Island, Alaska, in 1906-07. They lost their ship, but in a sledge journey over the ice they located the continental shelf of the Arctic Ocean, 65 miles offshore, where in 2 miles the sea increased from 50 meters to more than 680 meters in depth.

Organizing an expedition to map out the northeast coast of Greenland, to recover the bodies of Mylius-Erichsen (q.v.) and Lieutenant Hög-Hagen and their records, Mikkelsen wintered (1909-10) at Shannon Island, East Greenland. His ship sank, and the rest of the party returned home on a whaler. Remaining with his engineer, Iversen, Mikkelsen succeeded

by a series of most remarkable and hazardous sledge journeys in recovering the lost records and in disproving the existence of Peary Channel. The two explorers, who later wintered at Shannon Island, were rescued, when in the direst of extremities, by a Norwegian whaler (1912). Mikkelsen's writings are: *Conquering the Arctic Ice* (1909); *Lost in the Arctic* (1913; Ger. trans., 1913); "Mylius-Erichsen's Report on the Non-Existence of Peary Channel," in *Meddelelser om Grønland*, vol. xli., (1913); *The aar paa Grønlandsøstkyst* (1914).

MIKLOSICH, mik'lo-shich, FRANZ VON (1813-91). A famous Slavic philologist of Slovene nationality. He was born in Luttenberg, Styria, studied law at Gratz, and settled to practice in Vienna in 1838. There the famous Kopitar (q.v.) aroused in him an interest in Slavic philology, and he first attracted attention by his review of Bopp's *Comparative Grammar* in 1844. Henceforth he devoted himself to philology, and until his death his productivity was enormous. In 1844 he obtained a position in the Imperial Library and in 1850 was made professor of Slavic philology in the University of Vienna, retaining his post until 1886. He was also government censor of Slavic, Rumanian, and Greek publications. His scientific career is remarkable for profundity of research. Miklosich is not only the founder of modern Slavic philology, but he also greatly promoted the historical study of the Albanian, Gypsy, Hungarian, modern Greek, and Rumanian languages. Aside from numerous articles on special points of phonetics, syntax, archæology, etc., chiefly published in the *Denkschriften* and the *Sitzungsberichte* of the Vienna Academy of Sciences, the most important of his works are: *Vergleichende Grammatik der slavischen Sprachen* (1852-74; 2d ed. of vols. i, iii, iv, 1876-83); *Formenlehre der altslowenischen Sprache* (2d ed., 1854); *Lexicon Palæoslovenico Græco-Latinum* (2d ed., 1865), one of the best of its kind for completeness and the abundance of material; *Altslowenische Formenlehre in Paradigmen* (1874); *Altslowenische Lautlehre* (3d ed., 1878); *Etymologisches Wörterbuch der slavischen Sprachen* (1886). Miklosich also edited several important texts, such as: *Apostolus* (1853); *Lex Stephani Dušani* (1856); *Monumenta Linguae Palæoslovenicæ e Codice Suprasliensi* (1857); *Monumenta Serbica* (1858); *Acta et Diplomata Græca Medii Ævi* (1860-87), with J. Müller. Consult: Jagić, *Encyklopediia Slavianskoi Filologii*, vol. i (St. Petersburg, 1909).

MIKLÚCHO-MACLAY, mé-klóv'kó-má-klí', NIKOLAI (1846-88). A Russian traveler and ethnographer, born in the Ukraine of a noble family. He studied medicine and zoölogy at St. Petersburg and in Germany. After traveling widely in Europe he went with Haeckel to Madeira (1866), visited the Canary Islands in 1867, and after a trip to Morocco in 1870 undertook a great anthropological tour in Oceania. At Sydney he founded a museum and zoölogical station and in 1885 returned to St. Petersburg, where he died before he had classified his collections. He wrote on his travels in New Guinea in Petermann's *Mitteilungen* (1874, 1878) and on the temperature of oceanic depths for the *Bulletin* of the St. Petersburg Academy (1871), and made many other contributions to technical journals in Europe, Asia, and Australia.

MIKNAS, mik'nás. A town of Morocco. See MEQUINEZ.

MIKOVEC, má'kó-véts, FERDINAND BRITISLAV (1826-62). A Bohemian dramatist and archæologist, born at Bürgstein and educated at Česká Lípa and Prague. He founded the literary journal *Lumír* (1851-64) and edited two volumes of Bohemian antiquities under the title *Starožitnosti a památky země české* (1858-64). He wrote the tragedies *Záhuba rodu Přemyslovského* (The Fall of the Přemyslids, 1851), *Dimitri Ivanovič* (1856), and other dramatic works.

MILAN, mil'an or ml-lán' (It. *Milano*, Lat. *Mediolanum*). The second-largest city in Italy, the chief city in Lombardy, and the capital of the Province of Milan. It is situated in the great plain of Lombardy, 400 feet above the sea, on the little river Olona, an affluent of the Po, 93 miles northeast of Turin and 166 miles west of Venice; lat. 45° 28' N., long. 9° 11' E. (Map: Italy, B 2). The climate is rather changeable and trying. It is extremely hot in summer and quite cold in winter, the winds from the frozen Alps sweeping across the Lombardy plain. The thermometer at times drops below zero. The mean annual temperature is 55.4° F.; rainfall, 39.37 inches.

Milan is a fairly symmetrical polygon in shape, the circuit of its customs district being now nearly 20 miles. Its focus is the splendid Piazza del Duomo (Cathedral Square), from which broad avenues and electric railways radiate in all directions. These radials are connected by an inner circle of modernized streets just outside the canal that marks the location of the ancient moat and of the inner and most ancient city. An additional connection is furnished by a splendid boulevard and by a belt electric railway 7 miles long beyond the sixteenth-century walls that are pierced by a dozen gates and are now planted with trees and used as a promenade, commanding the view of the suburbs. The most magnificent of the radials is the modern Via Dante, constructed in 1888, leading from the handsome Piazza de' Mercanti to the spacious Foro Bonaparte, and thence to the New Park, which was formerly a part of a national drill ground. This park is paved with wooden blocks on a concrete foundation, and on each side, next to the front foundation walls of the houses, has large subways containing water and gas pipes, electric wires, etc. It is beautified by a large pond and spacious promenades, and is faced by the Castello Sforzesco, and also by the Anfiteatro dell' Arena, which was constructed by Napoleon I for races and is capable of seating 30,000 persons. The park is lighted by electricity. Adorning the northeastern section of the city are the splendid Giardini Pubblici, surpassed by few gardens on the Continent. The Corso Vittorio Emanuele is one of the most elegant shopping streets in Italy and the centre of traffic in Milan. The Galleria Vittorio Emanuele, connecting the Piazza del Duomo with the Piazza della Scala, is a splendid glass-covered arcade, with shops, designed by one of Milan's distinguished architects, Mengoni. It is in the form of a Latin cross, with a cupola 160 feet in height.

Architecture is superbly represented in Milan, nearly all styles being displayed in rare examples. Bramante dwelt here many years and left his genius impressed on more than one fine monument. The city is particularly famous for fine churches. Of these the principal is the world-renowned Gothic cathedral, the Duomo of

Milan, one of the finest of ecclesiastical structures, ranking with St. Peter's at Rome and the cathedral of Santa Maria del Fiore at Florence. The vast church has an exterior of white Carrara marble, which is adorned by 98 pinnacles and with more than 4000 statues, besides a variety of carvings of unsurpassable beauty. In form it is a Latin cross, with a length of 486 and a breadth of 287 feet, and covers an area of 14,000 square yards. The height of the tower is 350 feet. The great windows of the choir, said to be the largest in the world, are of stained glass of 1844. Its foundation was laid in 1386 by Gian Galeazzo Visconti, and during its erection many of the greatest European architects contributed designs for its embellishment. Within it Napoleon was crowned King of Italy in 1805. The baroque façade, completed in 1805 after designs by Tibaldi, has been considered out of harmony with the Gothic style of the other portions of the structure, and the inharmonious features began to be removed in 1900, to be replaced by features in keeping with the general style of the structure. At the front of the cathedral is a colossal bronze statue of Victor Emmanuel II. The view of the Alps, Lombardy, and the city from the top of the cathedral is celebrated. The quaint mediæval church of Sant' Ambrogio, erected on the site of a church founded by St. Ambrose in the fourth century, possesses inscriptions, sarcophagi, and monuments full of antiquarian interest, and is historic as the place where St. Ambrose baptized St. Augustine and where the German emperors were crowned kings of Italy. There are also the Dominican church of Santa Maria delle Grazie, which contains in its refectory the now almost obliterated picture of the "Last Supper" by Leonardo da Vinci; the church of San Carlo Borromeo (1847); and San Nazaro, which possesses a masterful fresco by Lanino, and also San Sebastiano, once a Roman temple. The church of San Satiro has a beautiful sacristy—a creation of Bramante. The mural paintings of Luini in the church of San Giorgio al Palazzo are visited by all art lovers. San Lorenzo is an important church, and is in addition the oldest one in the city, tracing its history back to Roman times.

Of the secular buildings of Milan the most noteworthy is the magnificent Brera Palace, formerly a Jesuit college and now used for the fine arts, with the official name of Palace of Arts and Sciences. (For illustration, see *LOMBARDY, RENAISSANCE ARCHITECTURE OF*.) Within its vast precincts this unique institution includes an academy of art, a choice gallery of paintings of the Bolognese and Lombard schools, a fine collection of casts for modeling purposes, a splendid national library containing about 300,000 volumes and pamphlets, and a rare collection of coins numbering 60,000, with many rare manuscripts and antiquities. It has also attached to it an observatory and a botanical garden. The masterpieces of painting here include Raphael's far-famed "Sposalizio," Mantegna's "Pietà," and Bellini's "St. Mark." The Brera has been greatly enlarged latterly, and many pictures of high rank have been added to its collection. One of the features of the national library is a room devoted to the editions and autograph writings of Manzoni. Another large library is the Ambrosian (q.v.). The Borromeo Palace also has a meritorious collection of paintings. The Museo Poldi-Pezzoli offers a fine collection of

paintings, weapons, furniture, porcelain, etc. The Museo Civico is worthy of mention for its superb ornithological collection. There is also a permanent art exposition, and Milan now has good scientific collections.

The Palazzo Reale and the archiepiscopal palace are old and have some attractive features. The fine and elaborate Castello di Porta Giovia dates from 1308 and is the castle of Milan, being associated with the city's governmental and historic career. Among the noteworthy new and attractive secular buildings are the Exchange, finished in 1901, the prefecture, and Palace of Justice. Notable features in the city also are the Court of the Marino Palace, the Corinthian Colonnade, the finest relic of Roman times in Milan, and the well-known triumphal arch begun by Napoleon I. Other conspicuous public monuments are the statues of Victor Emmanuel II and of Cavour, Canova's notable statue of Napoleon I, the huge equestrian statue of Garibaldi, an equestrian statue of Napoleon III in commemoration of Magenta, the monument to Leonardo by Magni, the statues of Cardinal Borromeo and Parini, and the monument to Manzoni. The Cimitero Monumentale, with its decorative tombs and its elaborate cremation temple, is visited by all tourists. Milan is famous for its vast Scala Theatre, which was built in 1178 for operas and ballets. It accommodates 3600 persons and is the largest theatre in Europe after the San Carlo at Naples. Milan is the centre for music in Italy. The famous Conservatory of Music is established in the buildings of an ancient monastery.

Milan has an Academy of Science and Literature, a college for girls, and medical, high, and normal schools. The fine polytechnic, dating from 1865, a commercial academy, an agricultural school, a royal astronomical observatory, and an Accademia di Belle Arti are other educational institutions. There are also a municipal zoological collection, botanical gardens, and theatres. The government of the city is highly efficient and enormous sums have been expended on public improvements. The system of sewers, about 50 miles in length, empties into the swift covered-over Seveso, whence the sewage passes to the Adriatic by way of the Po. The city water for domestic purposes comes principally from large artesian wells, about 150 feet in depth, and for industrial purposes from the canals. The different philanthropic organizations under the control of the Board of Charities have property valued at over \$53,000,000 and a yearly income of \$1,600,000. The municipal schools are well organized, with 80 buildings and 50,000 pupils, in addition to which are evening schools attended by over 10,000 older pupils. The Maggiore hospital is one of the largest in the world, accommodating 4000 patients. It dates from 1456. There are deaf-and-dumb institutions and institutions for surgical operations and for ailments of the eyes. Milan has also public dormitories, soup kitchens, etc. The Milan poor suffer greatly from overcrowding. An official investigation showed that 38,000 families were living in one room each and that 333,000 persons, or 70 per cent of the population, were living in 172,417 rooms. Thousands of these rooms had no light except through the entrance door. In 1905 the citizens voted for municipal construction of houses for the working people, providing for an expenditure of \$1,000,000 for the erection of 48 tenement houses to

MILAN
THE CATHEDRAL

1

contain 500 apartments of one, two, and three rooms each. The Humanitarian Society also appropriated \$400,000 for the building of model tenements.

Milan is the leading financial city of Italy and possesses vast wealth. It markets large quantities of grain, cheese, butter, eggs, and poultry, and its manufactures include silk, leather, and woolen goods, stationary engines, locomotives, railway machinery, steam boilers, motors, automobiles, carriages, furniture, glass and earthenware, and chemical products. Cotton weaving and dyeing are also an important industry. A royal mint and a royal tobacco factory are situated here, and there is a corn exchange. It is the centre also of the Italian book trade. Not only are its industries by far the most important in Italy, but its commerce is very extensive. The Grand Canal connects the navigable Olona with Lake Maggiore and the Ticino. The city is also in canal communication with the Po, and with Lake Como through the Adda. It is an important centre of the national railway system. Milan is connected by street railways with the neighboring towns of Lombardy. The local system of electric street railways is excellent. In the last 20 years of the nineteenth century Milan grew more rapidly than any other Italian city. Pop., 1810, 124,000; 1860, 191,000; 1881, 321,839; 1901, 491,460; 1911, 599,200.

History. Livy (v, 34) declares that Milan, the ancient Mediolanum, or Mediolanium, was founded in the time of Tarquinius Priscus by Gauls who had come over the Alps. The ancient name is regarded as Celtic. Milan appears first definitely in history in 222 B.C., when it was taken by the consuls Cn. Scipio and Marcus Marcellus from the Gauls. Later, the town sided with Hannibal; its final and complete submission to Rome dates from 196 B.C. Its inhabitants became Roman citizens in 49 B.C.; in the second century A.D. it was colonized from Rome. Since roads ran from the city in all directions its trade rapidly increased. It rose to great prominence at the close of the third century A.D., when Diocletian made it the capital of Italy. Thereafter Milan was frequently a favorite Imperial residence. It was from Milan that Constantine issued in 313 the famous edict by which Christianity was recognized. Milan became the seat of a bishop, and from 374 to 397 this office was held by the celebrated Ambrose (q.v.). He established a ritual which in some points varied considerably from the Roman, and for a time Milan was the religious metropolis of northern Italy and almost entirely independent of Rome. This first era of prosperity was destroyed by the barbarian invasions by Attila (q.v.) in 452, by the Heruli under Odoacer in 476, and by the Goths under Theodoric in 493. In 539 the city was laid waste by the Goths so completely that but few remains of the city of Roman times have been found; these include a theatre, much below the present level of the ground. Many inscriptions, however, showing clearly the Celtic character of the population have been found; for these see the *Corpus Inscriptionum Latinarum*, vol. v. Only in the tenth century did Milan begin to recover.

During the greater part of the Middle Ages the population of Milan was divided into great nobles (*capitanei*), petty knights (*valvassores*), and the general populace. For a long time the history of the city turns upon conflicts between

these various classes. In 1036 the Archbishop Aribert sought to make himself independent of all ecclesiastical and temporal control and for this purpose united with the *capitanei*. He was, however, opposed by the Emperor Conrad II, who was aided by the *valvassores*. The Emperor in 1037 captured and imprisoned Aribert, but he escaped after two months, and the death of Conrad in 1039 put an end for a time to the conflict. But a long-continued revolt against Aribert resulted in the people's obtaining a share in the government. Henry III (1039-56) ruled the whole Empire (Italy included) with a firm hand, but during his reign the forces developed which resulted in the great conflict of the *Patavia* after his death. According to the Ambrosian rules priests were permitted to marry, but Hildebrand (later Pope Gregory VII) attempted to establish sacerdotal celibacy and also sought to connect the church of Milan more closely with that of Rome. He was aided in this attempt by the lower classes of the populace, who were known as *patarini*, i.e., ragamuffins, and were in reality infected with the Manichean heresy. Opposed to this whole movement were the Archbishop and his party, supported by the Emperor, Henry IV (1056-1106), who was also at war with the papacy. The conflict was violent, but terminated with a compromise, by which marriage of priests was forbidden for the future, but those who were married were allowed to retain their wives. The independent position of the archbishops, however, was gone forever, and the way was clear for the establishment of a republican commune, especially as a very powerful artisan class had gradually developed.

By the end of the eleventh century Milan was practically free from external government and was ruled by consuls elected by the three orders; it rapidly acquired a hegemony over the other Lombard cities. When, however, Frederick Barbarossa became Emperor he proceeded to reestablish the old Imperial power in Italy, and in 1153 began with Milan. Twice the city was compelled to submit, in 1158 and 1162, and the last time it was razed to the ground. The cities of northern Italy, which at first had been glad to witness the destruction of a rival, now, however, saw their own danger and hastened to the assistance of Milan under the leadership of Pope Alexander III. The Lombard League was formed against the Emperor, and in 1176 Frederick was defeated at Legnano, and in 1183 by the Peace of Constance recognized the independence of Milan and the other cities of Lombardy. After these foreign dangers were averted intestine strife again broke out between the various factions—the plebians, who had united in the *Credenza di Sant' Ambrogio*; the merchants; the lesser nobles, or *motta*; the great nobles, or *Società dei Gagliardi*. Wearied by these continuous quarrels, the citizens began to call in foreigners to rule and mediate, thus giving rise to the office of the *podestà*. In 1226 the Lombard League was renewed to prevent the aggressions of Frederick II, who was finally defeated in 1237 at the battle of Cortenuova.

In the thirteenth century Milan gradually lost its republican liberties. In 1259 the Guelph leader Martino della Torre headed the citizens in a struggle against the Ghibelline nobles and temporarily assumed the lordship of the city. But in 1277 a revolution was effected by the Ghibellines under the Archbishop Otto Visconti, who in turn became the ruler of the city, and at

his death in 1295 the power passed to his nephew Matteo Visconti, who had already been appointed Imperial vicar of Lombardy. From that time the Visconti (q.v.) ruled Milan almost continuously until 1447. Under their supremacy was not only Milan, but the whole of Lombardy; the arts were fostered and prosperity was general. In 1395 the Emperor Wenceslas granted Gian Galeazzo Visconti the title of Duke of Milan. The last of the Visconti, Filippo Maria (1412-47), after a short-lived republic, was succeeded in 1450 by his son-in-law, the celebrated *condottiere* Francesco Sforza (q.v.). The Sforzas were the typical princes of the Renaissance, patrons of art and learning, but at the same time guilty of the greatest cruelties. Milan became involved in the many Italian wars of the period, and finally Lodovico Sforza called in Charles VIII of France, who entered Italy in 1494. From this time on the history of Milan as such has little interest. Louis XII of France, as the descendant of the Visconti, claimed Milan, and the city and duchy for a while changed hands repeatedly between the French and the Sforzas, the latter being supported by Spain. In 1535 the last of the male line of the Sforzas died and Milan became a Spanish possession. In 1713 the Peace of Utrecht, which ended the War of the Spanish Succession, gave Lombardy to Austria. In 1797 Milan became the capital of the Cisalpine Republic, founded by Napoleon, and in 1805 the capital of the Napoleonic Kingdom of Italy. The Congress of Vienna in 1815 gave Lombardy back to Austria, and Milan shared with the rest of the Hapsburg possessions the oppressions of the Metternich régime. On March 18, 1848, the inhabitants rose in insurrection, and on March 23 General Radetzky was compelled to evacuate the city, which was occupied by the Sardinian forces. On August 6, however, Radetzky reentered Milan. The riots of March, 1849, and Feb. 6, 1853, were vigorously suppressed by the Austrian commanders. In 1859, after the battle of Magenta, the Austrians evacuated the city, which was handed over to Napoleon, who surrendered it to Sardinia with the rest of Lombardy. In May, 1898, it was the scene of serious bread riots.

MILAN, mī'lan. A city and the county seat of Sullivan Co., Mo., 112 miles by rail northeast of Kansas City, on the Quincy, Omaha, and Kansas City and the Chicago, Burlington, and Quincy railroads (Map: Missouri, C 1). It is in a farming and stock-raising region, which has some mineral deposits, particularly of coal. The principal industrial establishments are the coal mines and the shops of the Quincy, Omaha,

and Kansas City Railroad, Milan being a division point on that road. The water works and electric-light plant are owned by the city. Pop. 1900, 1757; 1910, 2191.

MILAN DECREES. See CONTINENTAL SYSTEM.

MILANESI, mè-là-nà'zè, GAETANO (1813-86). An Italian art historian, born at Siena. He studied law in his native city; was employed in a public library; and in 1856 became a member of the Accademia della Crusca. In 1858 he was made assistant keeper of the Tuscan archives at Florence; later took charge of the Medici archives; and in 1869 was appointed director of archives. He retired in 1892. Besides preparing an important edition of Giorgio Vasari's *Vite de' più eccellenti pittori, scultori, ed architetti* (9 vols., 1878-85), and *Le corrispondenti di Michel Ange*, only 1 vol. of which ("Sebastiano del Piombo," 1890) appeared, Milanese published: *Il diario inedito di Alessandro Sozzani* (1842); *Documenti per la storia dell' arte senese* (3 vols., 1854-56); *Discorsi sulla storia civile ed artistica di Siena* (1862).

MILANÉS Y FUENTES, mè'lá-nás' é fwán'tás, JOSÉ JACINTO (1814-63). A Cuban poet, born at Matanzas. His first verses appeared in the *Aguinaldo Habanero* (1837) and were favorably received. From this time his work was well known. His early life had been one of poverty and hardship, but afterward he obtained a satisfactory position and was able to travel abroad in 1848. He had been the victim of a mental disease for some time, and during the last years of his life was quite insane. The poetry of Milanés is contemplative and melancholy and, like that of his fellow poets Heredia and Plácida, saddened by the thought of his country's wrongs. Editions of his poems were published at Havana (1846) and New York (1865), the latter with biography and criticism by Federico Milanés.

MILAN OBRENOVITCH (mē'lan ó-brén'óvitch) IV (i.e., fourth in the Obrenovitch (q.v.) family) (1854-1901). Prince of Servia from 1868 to 1882 and King from 1882 to 1899. He was born Aug. 22, 1854, at Manassee, Rumania, and was educated at Paris. The assassination of Prince Michael III in 1868 caused his recall to Servia, where he was proclaimed Prince. A council of regency administered the government till he was 18. The revolt of Servia against the Ottoman power, its alliance with Russia in the Russo-Turkish War (q.v.), and its resulting independence and recognition as a kingdom (1882) made his reign memorable. In 1875 he married Natalie Ketchko, the daughter of a Russian colonel, and his quarrels with her and his personal vices deprived him of all prestige. In 1888 he was illegally divorced, and on March 6, 1899, he abdicated in favor of his son Alexander I (q.v.). He became reconciled to Natalie in 1893 and died at Vienna, Feb. 11, 1901. See SERBIA.

MILÁ Y FONTANAIS, mè-lá' é fón'tá-ná'w'. MANUEL (1818-84). A Spanish historian of literature, born at Villafranca del Panadés. He was appointed professor in the University of Barcelona in 1845. He did not obtain wide celebrity until he was appointed president of the Floral Games at Barcelona in 1859. The influence of his philosophical studies is apparent even in so early a work as his *Arte poética* (1848). This was followed by the *Romances*

castán (1848), a collection of the lyrics of his native region, and by the *Elementos de literatura* and the *Teoría literaria*, which apply philosophical methods to the study of literature. His *Observaciones sobre la poesía popular* appeared in 1853. His noblest productions are *Los trovadores en España* (1861) and *La poesía heroico-popular* (1874). Consult: Rubió y Ors, *Noticia de la vida y escritos de D. Manuel Milá y Fontanals* (Barcelona, 1887), and the edition of his *Obras completas* (id., 1885), prepared by M. Menéndez y Pelayo, who never wearied of praising Milá y Fontanals as a great scholar and a great teacher.

MILAZZO, mé-lát'só, or **MELAZZO**. A city in the Province of Messina, Sicily, 16 miles by rail west of the city of Messina, at the base of a narrow peninsula, 4 miles long (Map: Italy, E 5). It has a very large and safe harbor which serves as a refuge for vessels trying to make the north entrance of the Strait of Messina. Its thirteenth-century castle is now used as a jail. It has a city hospital, a technical school, a city library of 10,000 volumes, and a municipal theatre. It markets wine, fish, cattle, fruit, and sulphur and has a considerable foreign trade and extensive tunny fisheries. Pop. (commune), 1910, 16,422; 1911, 16,569. Milazzo is on the site of the ancient *Mylæ*, founded prior to the eighth century B.C. by colonists from Messina. A great naval victory was won here over the Carthaginians in 260 B.C. by G. Duilius. The crowning point of Garibaldi's victorious Sicilian campaign was his defeat of the Neapolitans here, July 20, 1860.

MILBANK, JOSEPH (1848-1914). An American philanthropist, born in New York City. Between 1896 and 1903, together with his sister, Mrs. Elizabeth Milbank Anderson, he gave \$3,000,000 to Teachers and Barnard colleges, Columbia University. Connected with the former is Milbank Memorial Chapel and with the latter Milbank Hall. In 1901 he established the Milbank Baths at a cost of \$150,000, and in 1905 he gave \$200,000 to found the Jersey City People's Palace, a clubhouse for the people under the control of the First Congregational Church of Jersey City. With his sister he gave \$650,000 to establish a Social Welfare Bureau and \$500,000 to the Children's Aid Society. In all they gave nearly \$5,000,000.

MILBURN, WILLIAM HENRY (1823-1903). An American clergyman. He was born in Philadelphia and educated at Illinois College. He entirely lost the sight of one eye and partially that of the other while he was a boy, and finally became wholly blind. He became a minister of the Methodist Episcopal church in 1843 and was appointed to circuits in Illinois and the South, with several appointments at Montgomery, Ala., in 1848, and Mobile in 1850, and for two years after 1852 preached in an independent church. He was ordained a deacon in the Protestant Episcopal church in 1865 and priest in 1866, but returned to the Methodist Episcopal church in 1871. He was elected chaplain of Congress in 1845 and 1853, chaplain of the House of Representatives in 1885 and in succeeding terms, and was chaplain of the Senate from 1893 to 1902. He published *Rifle, Axe, and Saddlebags, Symbols of Western Character and Civilization* (1856); *Ten Years of Preacher Life, Chapters from an Autobiography* (1858); *Pioneers, Preachers, and People of the Mississippi Valley* (1860), comprising lectures

given at the Lowell Institute in 1854; *The Lance, Cross, and Canoe in the Valley of the Mississippi* (1893).

MIL'COM. The national god of Ammon, mentioned in 1 Kings xi. 5, 33; 2 Kings xxiii. 13; Jer. xlix. 13; probably 2 Sam. xii. 30; and also 1 Kings xi. 7, where the true reading seems to be supplied by the Greek version. The name is clearly derived from *melek*, 'king,' and the final *m* probably represents the old determinative mimation. If Milcom was the original reading in 2 Sam. xii. 30, it would seem to indicate that the Ammonitish god was represented by an idol in human form. There is no evidence that this deity was also called Molech (q.v.) or that children were sacrificed to Milcom, though it is not in itself improbable that this rite was practiced by the Ammonites on extraordinary occasions, as it certainly was by their kinsmen, the Moabites. (See **MOAB**.) Solomon erected a sanctuary to Milcom on the Mount of Olives, possibly on the site of the present *Jebel batn el hawa*, which Josiah afterward defiled. (2 Kings xxiii. 13.)

MILDER-HAUPTMANN, mél'dér-houpt'mán, ANNA PAULINE (1785-1838). A German opera singer, born at Constantinople, the daughter of an Austrian attaché. She studied under Tomascelli and Salieri in Vienna; made her first appearance in that city in 1803, but was at the height of her power in Berlin (1815-29). She toured Russia, Sweden, and Denmark at the close of her stage career. She was one of the earliest examples of a great vocalist possessed at the same time of extraordinary histrionic ability. For this reason Beethoven chose her to create the rôle of Leonora in his *Fidelio*.

MILDEW (AS. *meledæaw*, honeydew, from **mele*, Goth. *milip*, Lat. *mel*, Gk. μέλι, *meli*, honey + *dæaw*, dew). A somewhat indefinite term used to designate a number of plant diseases that are caused by fungus parasites, as well as spots caused by microscopic fungi on cloth, paper, leather, glassware, etc. In England the term as applied to plant diseases has a much wider significance than in the United States. It is there made to include what are known in America as cereal rusts and smuts, as well as many other diseases not recognized as due to the mildews proper. In the United States the mildews are divided into two classes: the true or powdery mildews, due to fungi belonging to the family *Erysiphacæ*; and the false or downy mildews caused by fungi of the family *Peronosporacæ*. The powdery mildews attack the leaves, stems, flowers, and fruits of many of the most valued plants. For the most part they form superficial flourlike patches of white upon their host plants. The fungus most commonly develops over the surface of the leaves and sends minute suckers into the epidermis, by which they absorb nourishment from the host. They cause distorted and stunted growth and often the death of the part of the plant affected. During the summer the fungus sends up numerous branches, which bear myriads of one-celled spores called conidia, by which the mildew is rapidly spread to other plants. Later in the season thick-walled resting spores are produced, by which the fungus is carried through the winter. These spores have appendages of various kinds, by which they retain their attachment to the leaves, and in the spring they develop a new generation of thin-walled spores for the spread of the disease. There are about 150

described species of powdery mildews, and there are very few plants that are not subject to attack from some of them. Among the common ones injurious to economic plants are the apple, pear, and cherry mildew (*Podosphera oxycantha*), rose mildew (*Sphaerotheca pannosa*), hop mildew (*Sphaerotheca castagnei*), grape mildew (*Uncinula spiralis*), mildew of wheat and other grasses (*Erysiphe graminis*), gooseberry mildew (*Sphaerotheca mors-uvæ*), cucumber mildew (*Erysiphe cichoracearum*), which also attacks verbenas, sunflowers, asters, and other plants, pea mildew (*Erysiphe polygomi*), etc. Downy mildews are internal parasites which grow through the tissues of the plants that bear them and only appear outside to shed their microscopic spores. The branches of the fungus bearing these spores are often so abundant as to give a peculiar downy or frosty appearance to the leaf or other part of the plant infested. The spores (conidia) are one-celled, thin-walled, and readily blown about by the wind. Falling upon a new leaf or plant, if the moisture conditions are favorable, they quickly germinate and set up a new infection. In this way they spread with great rapidity and often produce epidemic outbreaks of disease. The resting spores are formed within the tissues of the host and are thus carried over from season to season. They are liberated by the decay of the tissues surrounding them, and from these a new generation is derived. Among the downy mildews are some of the most serious plant parasites. The more common ones are the potato rot or mildew (*Phytophthora infestans*), the grape downy mildew (*Plasmopara viticola*), lima-bean mildew (*Phytophthora phaseoli*), lettuce mildew (*Bremia lactuæ*), onion mildew (*Peronospora schleideni*), beet mildew (*Peronospora schachtii*), cucumber and melon downy mildew (*Plasmopara cubensis*), downy mildew of radishes and other cruciferous plants (*Cystopus candidus*), etc. Most of these mildews are more fully described under the diseases of their respective host plants. The problem of combating them has been a subject of much experimentation in America and in Europe. It has been found that many of the powdery mildews can be held in check and often serious loss prevented by dusting the plants with sulphur, or, if in a house or frame where it can be done, exposing them for a few moments to the fumes of boiling, but not burning, sulphur. Spraying thoroughly and repeatedly with Bordeaux mixture, ammoniacal copper carbonate solution, or other standard fungicide (q.v.) will prevent the serious attack of both classes of mildews. Success in these preventive treatments depends upon thoroughness. See DISEASES OF PLANTS; FUNGI, ECONOMIC; Plate of FUNGI, TYPES OF; PERONOSPORALES; PHYCOMYCETES.

MILE. A measure of length in common use in Great Britain and the United States and their colonies. The name was also in use in the continent of Europe to designate generally a much larger measure of length, although the official measure is now generally the kilometer (.6213 mile). The mile is derived from the Roman *milliare*, which contained 1000 paces (*mille passuum*) of 5 Roman feet each, the pace (*passus*) being the length of the double step (*gradus*) made by one foot from the time it was taken off the ground until it was put down again. The Roman foot being between 11.62 and 11.65 English inches, the Roman mile was

thus less than the present English mile by from 142 to 144 yards. The mile is found referred to in a law of King Athelstane (925-940 A.D.) and as a unit of length has not altered from before the Norman Conquest to the present time. On the continent of Europe previous to the general adoption of the metric system, the length of the modern mile in different countries exhibited a remarkable diversity not satisfactorily accounted for. In some cases, such as the Prussian mile, which was 4.68 statute miles, and the Swedish mile, equal to 6.648 statute miles, the length was far in excess of current understanding of the measure. Such miles, however, have long been obsolete and are only interesting to the student of metrology or the surveyor working on old maps. Before the time of Elizabeth scientific writers made use of a mile of 5000 English feet, from the notion that this was the Roman mile, forgetting the difference in value between the English and the Roman foot. The present English statute mile was incidentally defined by an act passed in the thirty-fifth year of the reign of Elizabeth to be "8 furlongs of 40 perches of 16½ feet each"—i.e., 1760 yards of 3 feet each—and it has since retained this value. The *geographic, nautical, or sea mile* is variously defined as (a) the length of a minute of latitude at any point, (b) the mean length of a minute of latitude (6082.66 feet), and (c) the length of a minute of longitude on the equator (6087.15 feet). The United States Coast Survey has adopted as the standard geographic mile the length of a minute of latitude of a sphere having the same surface as the earth. This gives a length of 6080.27 feet. The British Admiralty mile is 6080 feet. The United States nautical, sea, or geographical mile as given by the National Bureau of Standards (Circular 47, 1914) is 6080.20 feet. As the United States statute mile is 5280 feet, a nautical mile is 1.151553 statute miles, or 1853.249 meters. For ordinary purposes of navigation the nautical mile is assumed to be equal to a minute of latitude in the region navigated, the error being inappreciable in the calculations. See WEIGHTS AND MEASURES; METRIC SYSTEM; and the various authorities referred to thereunder.

MILE'AGE. Compensation reckoned at so much per mile in lieu of traveling expenses usually allowed public officers who are compelled to journey to the seat of government in order to discharge their official duties. It is usually reckoned according to the shortest route by which the officer is able to travel. American army officers traveling under orders are allowed seven cents a mile; Senators and Congressmen are allowed 20 cents a mile when traveling to the seat of government at the opening of a session and to their homes at its close. An abuse of the system is constructive mileage, allowed for distances not actually traveled, as when the time between the close of one session and the opening of another is too brief to admit of a return of Senators and Congressmen to their homes.

MILELLI, mè-lèl'li, DOMENICO (1841-1908). An Italian poet, born at Catanzaro in Calabria. His poetry shows much imagination, but little sustained force. His *Odi pagane* (1879) were much criticized, not only for their pagan spirit, but on account of attacks on Manzoni. Other works are: *In giovinezza* (1879); *Giocande* (1874); *Hiemalia* (1874); *Povertà* (1879); *Discrpta* (1881); *Il rapimento di Elena*

(1882); *Canzoniere* (1884); *Verde antico* (1885); and *Miscellanea* (1886), a volume of essays. Consult Patari, *L'opera poetica di D. Milelli* (Cosenza, 1912).

MILES, NELSON APPLETON (1839-1925). An American soldier, born at Westminster, Mass., Aug. 8, 1839. He received an academic education and between 1856 and 1861 was engaged in business in Boston. During the Civil War he rose from the rank of first lieutenant of the Twenty-Second Massachusetts Infantry to be major general of volunteers (Oct. 21, 1865). "For highly meritorious and distinguished conduct throughout the campaign and particularly for gallantry and valuable services at the battle of Reams Station, Va.," he was brevetted major general of volunteers (Aug. 25, 1864), and March 2, 1867, he received brevets of brigadier general and major general for services at Chancellorsville and Spottsylvania respectively. He had fought also at Antietam, Fredericksburg, and in the campaign before Richmond (1864). His conduct at Chancellorsville, where he had been seriously wounded, brought him the congressional medal of honor in 1892. After the war General Miles became an officer in the United States army, being appointed colonel of the Fortieth Infantry in July, 1866, and rising to be brigadier general (1880), major general (1890), and lieutenant general (in pursuance of an Act of Congress of June 6, 1900). Upon the retirement of General Schofield in 1895 he became senior officer commanding the army. During a period of about 15 years Miles was known chiefly for his distinguished services against the Indians in the West. In 1876 he defeated the Cheyenne, Kiowa, and Comanche tribes, and in 1873 the Sioux and Nez Percés in Montana. After his campaign (1886) against the Apaches, in which he compelled their chiefs, Geronimo and Natchez, to surrender, he received the thanks of the legislatures of Kansas, Montana, New Mexico, and Arizona. In 1890-91 he suppressed Indian outbreaks in South Dakota. During the railroad strike troubles of 1894 in Chicago he commanded the Federal troops ordered by President Cleveland to prevent interference with the carriage of the mails. Later he represented the United States army at the seat of the Turco-Grecian War, and on the occasion of Queen Victoria's Diamond Jubilee (1897). During the war of 1898 against Spain he directed in person the occupation of Porto Rico. Within two weeks the entire western part of the island was cleared, the total loss of Americans being only four killed and forty wounded. In 1902-03 General Miles made a tour of inspection in the Philippine Islands. He was retired Aug. 8, 1903. The degree of LL.D. was conferred on him by Harvard, Brown, and Colgate universities. He published *Personal Recollections, or from New England to the Golden Gate* (1897); *Military Europe* (1898); *Observations Abroad* (1899); *Serving the Republic* (1911).

MILES CITY. A city and the county seat of Custer Co., Mont., 114 miles by rail northeast of Billings, on the Chicago, Milwaukee, and St. Paul and the Northern Pacific railroads (Map: Montana, L 3). Farming, cattle and sheep raising, and the manufacture of saddlery are the chief industries. It is a jobbing centre and shipping point for considerable quantities of wool, and a large market for range horses. In 1914, 28,442 horses were sold here at auction. The water works and electric-light plant are

owned by the city. Miles City contains a county hospital, a beautiful park on the Tongue River, an Ursuline convent, a well-equipped high school, a State industrial school, and a public library. Pop., 1900, 1938; 1910, 4697; 1915 (state census), 7621.

MILES GLORIOSUS, mī'lēz glō'rī-ō'sūs (Lat., braggart soldier). A comedy by Plautus.

MILESIANS. The original Gaelic colonists of Ireland, so called, according to the bardic accounts, from the three sons of Mil (Latinized Milesius), who, coming in force from the opposite coast of Spain or Gaul, landed on the southern end of the island and defeated the preceding colonists and conquerors, the Tuatha De Danann, in two great battles, thus making themselves masters of the country. The date is indefinitely placed some centuries before the Christian era. This was the last of the traditional prehistoric colonizations of Ireland, the dominant Milesians fusing with the Tuatha De Danann (q.v.) and Firbolgs (q.v.) to form the Irish race as we find it at the dawn of history. The native kings, chieftains, and prominent families up to the period of the Norman Conquest all claimed direct descent from Milesian ancestry.

MILESIAN TALES (Μιλῆσιακά, *Milēsiaka*). The name given to a class of short, indecent anecdotes in vogue at Miletus and through Asia Minor in the first century B.C. The compilation of six books of these stories was ascribed to a certain Aristides of Miletus. Fragments of these works, from the translation by Sisenna (q.v.), are printed in Bücheler's small edition of Petronius (5th ed., Berlin, 1882). Consult H. T. Peck, *Trimalchio's Dinner*, pp. 20-32, 40-44 of the "Introduction" (New York, 1898), and L. C. Purser, *The Story of Cupid and Psyche as Related by Apuleius*, xix-xxi, pp. 125-127 (London, 1910).

MILET DE MUREAU, mē'lā' de mu'rō', LOUIS MARIE ANTOINE DESTOUFF, BARON (1756-1825). A French soldier and politician, born at Toulon. He entered the army and was made a captain. As a member of the States-General, in 1789, he voted with the Right; afterward he commanded the artillery in the army of occupation in Italy. He was made a brigadier general in 1796; was War Minister for a few months in 1799; was created Baron by Napoleon in 1809; served as a prefect of the Department of Corrèze in 1802-10 and director of the general War Department in 1814, but retired two years afterward. He edited the *Pérouse journals*, which were published under the title *Voyage de La Pérouse autour du monde 1785-88* (1797; 2d ed., 1798).

MILETUS (Lat., from Gk. Μίλητος, *Milētos*). Anciently the greatest city of Ionia (q.v.) in Asia Minor (Map: Greece, Ancient, E 3). It was situated on the Latmic Gulf, at the mouth of the Mæander, in a rich valley, and was famous for its woolen manufactures and for its extensive trade with the north and the south, and with Phrygia. The site is said to have been occupied by a Carian town when the Ionian colonists, under Neleus, seized the place, massacred the men, and took possession of their wives. Pottery found by Wiegand (see the bibliography below) proves that the city was in touch with the Ægean civilization in the latest Minoan period. (See *Αρχαιολογία*, II, *Minoan*, or *Ægean, Period*.) Though the inhabitants prided themselves on their Ionian descent, the names of their tribes show the presence of a foreign element. The

city early came to occupy a commanding position in the Greek commercial world and established many colonies in the north, as Abydos and Lampsacus, on the Hellespont; Cyzicus, on the Propontis; Sinope, Olbia, Istria, Tomi, and Panticapæum, on the Black Sea. Under the tyrant Thrasybulus it offered so resolute a resistance to the Lydian kings that it was at last received into an alliance on equal terms. By 500 B.C. it was one of the first Greek cities, if not actually the first. It took a prominent part in the Ionian revolt (500 B.C.; see IONIA), and after the battle of Lade was besieged by the Persians, and after a long resistance captured and destroyed in 494 B.C. It seems to have revived after the formation of the Athenian League, and near the close of the Peloponnesian War ventured to revolt and join the Spartans (412 B.C.). It also offered some resistance to Alexander, but seems to have declined from that time, though it continued to exist for several centuries. St. Paul spent two or three days there on his last journey to Jerusalem before his imprisonment at Rome, and delivered his farewell address to the elders from Ephesus, who visited him at his request. (Acts xx. 15-xxi. 1.) Another visit, referred to in 1 Tim. iv. 20, is best placed in a period later than that covered by the Book of Acts. In Roman times the city retained commercial importance, especially under Trajan. In time its four harbors were filled up by deposits made by the Mæander; Lade, once an island protecting the harbors, is now a hill several miles inland. Miletus has a distinguished place in the history of Greek literature, having been the birthplace of the philosophers Thales, Anaximander, and Anaximenes, of the historians Cadmus and Hecataeus, and of the poet Timotheus. Aspasia, wife of Pericles, also was born at Miletus. The site of the city itself is a swampy plain, occupied by the little Turkish village of Palatia. Excavations were begun for the Berlin Academy in 1899, by Th. Wiegand, and in spite of great difficulties have determined the course of the ancient walls, some streets, the Bouleuterion and part of the Agora, and other points important for the topography of the city. A theatre, the largest, perhaps, in Asia Minor, with 54 rows of seats, still rising 100 feet or more, has been uncovered; so, too, a stadium. On the southeast a large temple of Apollo Delphinus, with a central court surrounded by a triple colonnade, was found; in this building, the chief temple of the city, public records were kept. A sacred way, bordered by tombs, led to Didymi. (See BRANCHIDÆ.) Reports of the excavations are published in the *Sitzungsberichte der Akademie der Wissenschaft zu Berlin* for 1900 et seq. Consult also the unfinished work of Rayet and Thomas, *Milet et le Golf Latmique* (Paris, 1877 et seq.); Arnold von Salis, "Die Ausgrabungen in Milet und Didyma," in *Neue Jahrbücher für das klassische Altertum*, vol. xxv (Leipzig, 1910); K. Baedeker, *Konstantinopel, Balkanstaaten, Kleinasien, Archipel, Cypern* (2d ed., with map and plan, ib., 1914).

MILETUS, HECATEUS OF. See HECATEUS OF MILETUS.

MILETUS, HESYCHIUS OF. See HESYCHIUS OF MILETUS.

MILETUS, TIMOTHEUS OF. See TIMOTHEUS OF MILETUS.

MILLEY, JOHN (1813-95). An American Methodist Episcopal theologian. He was born near Hamilton, Butler Co., Ohio; graduated at Augusta College, Kentucky, in 1838; entered the ministry in the same year; and served churches in Ohio and eastern New York from 1838 to 1873, except during 1848-50, when he was teacher in Wesley Female College, Cincinnati. From 1873 till his death he was professor of systematic theology in Drew Theological Seminary. He was a member of the General Conferences of 1864, 1872, 1876, 1888, and 1892, and of the Centennial Methodist Conference of 1884, where he presented a paper entitled "The Work of the Christmas Conference of 1784." In 1886 he was the fraternal delegate to the General Conference of the Methodist Episcopal church, South. He was the author of a *Treatise on Class Meetings* (1851); *The Atonement in Christ* (1879), which advocates the governmental theory; *Systematic Theology* (1892-94). He was a progressive conservative, holding to the substance of the traditional Methodist theology, but introducing important and some even radical changes of view. He was the brother-in-law of Bishop Randolph S. Foster.

MILFOIL. An herb. See ACHILLEA.

MILFORD. A seaport in Pembrokeshire, Wales, on the famous Milford Haven, 6 miles from its entrance and 273 miles west of London by rail (Map: England, A 5). The haven is formed by an estuary running inland for 17 miles to Langwin (easily reached by vessels of 2000 tons), and varies from a mile to two miles in breadth. It is protected from winds by a girdle of hills; its lower reaches are well fortified. The distance of Milford, however, from the Channel, the highway of British commerce, is a serious disadvantage, and its trade is not commensurate with the natural advantages furnished by its excellently protected harbor. The town has passenger and cattle traffic with Irish ports, and an average of 2700 vessels of 575,000 tons' burden enter and clear annually. Area of docks, 60 acres; depth of water over sill (high tide), 34 feet. The proposition to make Milford the eastern terminus of the English transatlantic steamers has been discussed since 1790. It would shorten by several hours the time now necessary for reaching London. It has important and rapidly increasing fish and oyster industries. The United States is represented by a consul. The town owns its water and gas supplies. The haven is frequently mentioned in Shakespeare's *Cymbeline*. Henry VII, when Earl of Richmond, landed here in 1485, on his way to claim the crown. Pop., 1901, 5102; 1911, 6399.

MILFORD. A town in New Haven Co., Conn., 9 miles southwest of New Haven, on Long Island Sound, at the mouth of the Wepowaug River, and on the New York, New Haven, and Hartford Railroad (Map: Connecticut, C 5). It is an attractive summer resort, with fine boating and bathing facilities. Its noteworthy features include the Taylor Library, an interesting Memorial Bridge, erected (1889) on the two hundred and fiftieth anniversary of the town's settlement, a soldiers' monument, and the Broad Street Park of four acres. The leading industries are farming, seed growing, oyster cultivation, wood turning and sawing, and the manufacture of straw hats, gas meters, brass novelties, car furnishings, etc. Pop., 1900, 3783; 1910, 4386; 1920, 10,193.

Milford, called Wepowage by the Indians, was settled in 1639 by a company from New Haven and Wethersfield. In 1644 Milford became one of the six towns which constituted the confederate "Colony of New Haven," and in 1664 it came under the jurisdiction of Connecticut. Robert Treat, an early Colonial Governor, lived in Milford, and here, from 1661 to 1663, the regicides Goffe and Whalley were secreted. Consult "Early Milford," in the *Connecticut Magazine*, vol. v (Hartford, 1890).

MILFORD. A town in Kent and Sussex counties, Del., about 73 miles by rail south of Wilmington on Mispillion River and on the Philadelphia, Baltimore, and Washington Railroad (Map: Delaware, J 3). A steamship line also connects the town with Philadelphia. It is the shipping point for the surrounding agricultural and fruit-growing district and has various industrial interests, including large packing houses and manufactories of dental supplies and lumber products. Milford was founded in 1680 and was incorporated in 1787. The town owns its water works and electric-light plant. Pop., 1900, 2500; 1910, 2603.

MILFORD. A town in Worcester Co., Mass., 18 miles (direct) southeast of Worcester, on the Charles River and on the Boston and Albany and the New York, New Haven, and Hartford railroads (Map: Massachusetts, D 4). It has a fine Federal building, public parks, a splendid system of schools, a public library, and a hospital. The town is the distributing centre for a wide area and is noted as a manufacturing centre, its products including shoes, straw goods, bone cutters, foundry and machine-shop products, looms, rubber goods, etc. There are also extensive quarries of a high grade of granite, which is used in the construction of some of the largest buildings in the country and which is shipped in large quantities. The government is administered by town meetings, which convene at least twice a year. Pop., 1910, 13,055; 1914 (U. S. est.), 13,770; 1920, 13,471. Settled as early as 1669, Milford, with a population of 750, was incorporated as a separate town in 1780, having previously been the East Precinct of Mendon. Consult Ballou, *History of the Town of Milford* (Boston, 1882).

MILFORD. A town in Hillboro Co., N. H., 11 miles northwest of Nashua, on the Souhegan River and on the Boston and Maine Railroad (Map: New Hampshire, F 8). Milford is one of the largest granite-producing towns in the United States, having 27 firms in that business, and there are also manufactories of furniture, post-office equipment, baskets, celluloid, woolen cloth, towels, ice-cream freezers, and shoes. Ample water power is obtained from the Souhegan. The water works are owned by the municipality. Pop., 1900, 3739; 1910, 3939.

MILHAU, mē'lô'. A town of France. See MILLAU.

MILHAUD, mē'yô', GASTON (1858-). A French philosopher, born at Nîmes. He was at first an assistant professor of mathematics at the University of Montpellier, where he obtained a doctorate in letters in 1894 and became professor of philosophy in the same year. In 1910 he was appointed professor of the history of philosophy at the Sorbonne, Paris. He is author of *Leçons sur les origines de la science grecque* (1893); *Essai sur les conditions et les limites de la certitude logique* (1894; 2d ed., 1898); *Le rationnel* (1898); *Les philosophes-*

géomètres de la Grèce (1900); *Le positivisme* (1902); *Le progrès de l'esprit* (1902); *Études sur la pensée scientifique chez les Grecs et les modernes* (1906); *Nouvelles études sur l'histoire de la pensée scientifique* (1911).

MIL'IA'RIA (Lat. fem. sing. of *miliaris*, relating to millet, from *milium*, millet). A structural affection of the sweat glands, caused by an obstruction to the sweat secretion and generally accompanied by inflammation. It is classed with the skin diseases.

In *miliaria crystallina*, or *sudamina*, the non-inflammatory form, the lesion consists of minute, pearly vesicles set closely together, but always discrete, generally appearing on the neck, chest, and abdomen, but sometimes in other parts of the body. The vesicles appear rapidly and depart in a few days. Invasions of fresh crops may occur, thus continuing the eruption for weeks. The vesicles are collections of sweat under the superficial layers of the skin.

In *miliaria vesiculosa*, or *rubra*, inflammation occurs in the gland, and the vesicles appear as if raised on a red base. This is the *strophulus*, or *red gum*, of the ancients and is seen principally in children during hot weather and when excessively heavy clothing is worn.

Miliaria papulosa, or *lichen tropicus*, is commonly known as prickly heat. In this variety red, pointed papules are crowded together, with here and there a vesicle or pustule. It is accompanied by excessive sweating and annoying prickling and tingling. It is a tropical disease, of which a milder form is seen in this country.

The treatment of miliaria consists in removing heavy clothing, administering cool baths and saline diuretics, and applying locally soothing and astringent lotions, such as lead water, black wash, dilute vinegar, or powdered camphor mixed with starch or oxide of zinc.

MIL'IA'R'IUM AU'REUM (Lat., golden milestone). A gilded column of bronze near the rostra, towards the west end of the Roman Forum. On it were engraved the distances from the city gates of the main stations and cities on the great roads leading out of Rome. It was set up in 29 B.C. by Augustus as a record of the results of a survey of the Roman domain. Portions of an exquisite marble base, supposed to be the base of the Golden Milestone, were discovered on the spot in 1849. Consult R. A. Lanciani, *The Ruins and Excavations of Ancient Rome* (Boston, 1897).

MIL'IARY FEVER. See MILIARIA; SWEATING SICKNESS.

MIL'ICEVIĆ, mē'lē-chēv'itch, MILAN. See MILITCHEVITCH, DJAKOV MILAN.

MILICZ, mē'litch, or **MILITSCH**, OF KREMSIER (c.1325-74). A predecessor of John Huss. He was born at Kremsier, Moravia; entered holy orders and was attached to the court of the Emperor Charles IV; became a canon and later Archdeacon. In 1363 he resigned his appointments, giving himself up to preaching, and was very successful. He went to Rome in 1367 to expound his views as to ecclesiastical abuses, but was thrown into prison by the Inquisition, from which he was released by Pope Urban V on his arrival from Avignon in the autumn of that year. He returned to Prague, where he preached daily with greater success than ever till in 1374 he was summoned before the Papal Court at Avignon, upon complaint as to his orthodoxy, preferred by the clergy of Prague. He obeyed, and the complaint, after investiga-

tion, was dismissed. He died in Avignon on June 29, 1374. Consult Palacky, *Die Vorläufer des Hussitentums* (Prague, 1869), and Lechler, *Johann von Wiclif und die Vorgeschichte der Reformation*, vol. ii (Leipzig, 1873).

MILINDA. The Pali form of the name of the Græco-Bactrian King Menander (q.v.). In the literature of the Buddhists his name is important through a book entitled *Milindapañha* or "Questions of Milinda," a work which professes to give an account of a discussion between him and the Buddhist sage Nagasena. It has been translated into English by Davids, *The Questions of King Milinda* (Oxford, 1890-94).

MILIOUKOV, PAUL. See MILYUKOV, PAVEL.

MILITARISM. A term employed somewhat loosely to designate a tendency to subordinate civil to military considerations in the policy of the state. In time of peace the civil power is theoretically supreme: the military power is an instrument to be employed in the execution of civil policies. Practically, however, the constitutional position of the army may be so strong as to give it an important, or even paramount share in the determination of both domestic and foreign policy. This is especially likely to be the case where a nation is surrounded by powerful antagonistic nations. The German Empire presents the best modern instance of militarism, but all the great powers of continental Europe manifest in greater or less degree the characteristics of militarism.

The term is still more loosely used to designate an acceptance of the theory of the inevitableness of warfare, and of the policy of military preparedness. Militarism in this broad sense is the antithesis of pacifism in the narrow sense of a movement towards immediate and absolute disarmament. See IMPERIALISM; INDUSTRIALISM; PEACE MOVEMENT, *International*.

MILITARY ACADEMY, ROYAL. An establishment at Woolwich, England, through which must pass all candidates for the Royal Artillery and the Royal Engineers. See MILITARY EDUCATION.

MILITARY ACADEMY, UNITED STATES. The national institution for the theoretical and practical training of cadets for commissions in the United States army. It is situated at West Point, N. Y., on the west bank of the Hudson, 50 miles from its mouth, amid the picturesque peaks of the Highlands. This place has been occupied as a military post continuously since Jan. 20, 1778. (See WEST POINT for Revolutionary history of the locality and description of the modern post buildings, surroundings, etc.) The Academy itself had its origin in a resolution passed by Congress on Oct. 1, 1776, which appointed a committee to prepare a plan for "a military academy of the army," but the earliest proposal for a military school for the United States was that of General Knox (May, 1776). His plans were seconded by Col. Alexander Hamilton and approved by General Washington. On June 20, 1777, it was ordered that a Corps of Invalids organized as "a military school for young gentlemen previous to their being appointed to marching regiments" be instituted; which order was carried into effect almost immediately. General Washington was untiring in his efforts to establish the Academy, and it was at his request in 1781 that the Corps of Invalids was marched from Philadelphia to join the garrison at West Point, where an

engineer school, a laboratory, and a library had already been established. Two years later Washington again brought the idea of a military academy before his officers at Newburgh, and made a special reference to it in his message of Dec. 3, 1793. On May 9, 1794, his ideas and aspirations were crystallized in a law approved on that date, whereby was authorized the organization of a Corps of Artillerists and Engineers with two "cadets" to each company, and a school of instruction for them was established at West Point in the same year.

The buildings, used as an engineer school, laboratory, and library respectively before 1781, were in 1796 burned down, and thus for a time the work of the Academy was suspended. Instruction was resumed on Sept. 1, 1801, by order of the Secretary of War, who, on July 20 of that year, issued an order directing that all the cadets of the Corps of Artillerists should report at West Point for instruction. The faculty of the Academy at this time was made up of four army officers and a civilian, who acted as administrators and instructors. The actual creation of the Military Academy as it is known today occurred in 1802, under the authorization of an Act of Congress approved on March 16. West Point was selected for its location, and with a class of 10 cadets present it was formally opened on July 4, 1802. The bill authorized the establishment of a Corps of Engineers to consist of 5 persons, a major, 2 first lieutenants, 2 second lieutenants, and 10 cadets, with the pay of \$16 per month. Provision was also made for promotions in the corps, not to exceed 1 colonel, 1 lieutenant, 2 majors, 4 captains, 4 first lieutenants, and 4 second lieutenants: but it was also distinctly ordained that the entire corps should not exceed 20 officers and cadets. The following year an increase of 40 cadets was authorized, and, in 1808, 156 became eligible, but, owing to the lack of provision for them at the Academy, very few of them were enabled to report for instruction.

The Academy passed through many vicissitudes about this time, and in March, 1812, was without a single instructor. Students entered without any mental or physical examination and with little regard to age. The War of 1812, however, called the attention of the government to the pressing needs of the Academy. Only 71 students had been graduated in its first 10 years, and President Madison called the attention of Congress to the necessity of making the Academy a scientific as well as a military college, in consequence of which, on April 29, 1812, the Academy was reorganized upon the principles which underlie its present organization. In 1818 the rules approved by President Monroe went into effect and provided that the assignment of cadets to the different corps in the army and their relative rank must depend upon their general merits, to be determined by a competent board of examiners, and that cadets should not be promoted until after they had received a diploma. Col. Sylvanus Thayer was appointed superintendent of West Point in 1817, and succeeded in making the institution famous among the military schools of the world. In 1815 he was sent by the government to Europe to study military schools, and during the 16 years of his superintendency (1817-33) completely reorganized the curriculum of the United States school. He organized the system of divisions of classes into sections, organized the corps of

cadets into a battalion, and created the position of commandant of cadets. In 1833 he took issue with President Andrew Jackson regarding details of management and resigned his post. In 1838 it was again offered him, together with concessions that gave him almost absolute control, but he declined to accept. From this time on little change has been made in the organization of the Academy other than those natural to the progress of time. Thayer is justly regarded as the Father of the Military Academy; with him began the present era of the Academy's history.

The Civil War (1861-65) brought West Point into considerable prominence throughout the civilized world—so much so that since then its methods have been carefully studied by the experts of nearly every great European country. Every one of the commanding generals on both sides in the Civil War who earned high military honors was a graduate of West Point.

The authorized number of cadets for 1916 is 745, but unless the Law of 1910 making certain increases be reenacted, this number will afterward fall to 571; the number of officers and civilians on duty on Jan. 1, 1915, was 132. The course of instruction is to a large extent mathematical and professional. The curriculum is as follows (September 1-June 4):

First year (fourth class): mathematics, English, history, surveying, drill regulations, gymnasium.

Second year (third class): mathematics, French, drawing, military hygiene, drill regulations, riding, gymnasium.

Third year (second class): natural and experimental philosophy (physics), chemistry, electricity, geology and mineralogy, drawing, drill regulations, Spanish, riding, gymnasium.

Fourth year (first class): civil and military engineering, military, international, and constitutional law, hippology, riding, ordnance and gunnery (with machine-shop practice), Spanish, gymnasium.

The physical training of a cadet is most carefully attended to. Apart from the regular drills and target practice, he learns to swim, ride, box, fence, and wrestle. So far as the limited time will permit, he is allowed to take part in football, baseball, tennis, golf, and track athletics. Polo is compulsory for the first class.

Upon the completion of the course (June 12), cadets who have been two years at the Academy are allowed to go home on a furlough of two months. The remainder go into camp, during which they receive practical instruction in the exercises of the various arms of the service, including practice marches and tactical exercises. In addition, cadets of the third and fourth classes are taught dancing.

The superintendent is assisted by a military staff, and the instruction is given by an academic staff, consisting entirely of army officers, with the additional rank of professors, assistant professors, and instructors of the several departments in which they serve.

In 1902 the requirements for candidates seeking admission were raised. The increased requirements, while making entrance more difficult, greatly assist the student during his period of instruction at the Academy by reducing the amount of work he is called upon to do during his course. Under General Orders, No. 38, War Department, 1914:

"A candidate for admission to the United

States Military Academy from a State, District, or Territory may be excused by the Academic Board from the mental examination for admission upon one of the following conditions:

"1. That he present a properly attested certificate that he is a regularly enrolled student in good standing without condition in any university, college, or technological school accredited by the United States Military Academy, provided that the entrance requirements for the course he is pursuing in such institution require proficiency in subjects amounting to 14 units of the College Entrance Examination Board, which must include mathematics A₁ (algebra to quadratics), A₂ (algebra, quadratics and beyond), and C (plane geometry); English A (reading and practice) and B (study and practice), as outlined by the College Entrance Examination Board. A certificate indicating enrollment at an irregular time or for the specific purpose of obtaining such certificate will not be accepted.

"2. That he present a properly attested certificate of graduation from a preparatory school or public high school which is on the accredited list of one of the institutions referred to above, provided that he is thus certified to have established proficiency in subjects amounting to 14 units of the College Entrance Examination Board, which must include mathematics A₁, A₂, and C, and English A and B, as outlined by the College Entrance Examination Board. A certificate indicating graduation at an irregular time for the specific purpose of obtaining such certificate will not be accepted.

"3. That he present a properly attested certificate from the College Entrance Examination Board that he has passed 14 units of its examinations, including mathematics A₁, A₂, and C, English A and B, and history A (ancient history) and D (American history and civil government)." After 1915 ancient history will not be required.

The system of training officers at West Point is regarded as more complete than that of any other country; but perhaps the greatest difference is the West Point method of holding the student firmly to his studies during his four years' course.

One feature of the system of instruction at the Military Academy consists in the division of each class into sections of from 7 to 12 cadets each, to each of which sections an instructor is assigned. Each cadet thus recites every day in every subject of his course of study; the result is a hold on his achievement and progress which would be impossible of attainment with larger classes. Transfers to higher or lower sections are continually made; an industrious attentive cadet thus realizes that his work will be recognized by promotion to a higher place in the class. Conversely, a cadet who neglects his studies is sure to "go down." This competition is valuable, because the original rank of graduates among themselves in the army depends on standing at the Academy. At the close of the four years' course, cadets of the highest standing are recommended, in numbers varying from year to year with local conditions, for all the corps of the army; these almost without exception pass into the engineers; then come a few recommended for all branches except the engineers. The remainder are recommended for cavalry, field artillery, coast artillery, and infantry.

The cadet mingles little with the outside world, except in his furlough at the close of two years, so that the four most impressionable years of his life are spent in a training and environment well calculated to produce a thorough soldier. The Academy has been described as a model institution by many distinguished European military authorities, and in the reorganization of the methods of military instruction in England many of the West Point ideas were suggested. The West Point cadet uniform (see UNIFORMS, MILITARY) is the famous cadet gray. The total number of graduates from 1802 to 1914 inclusive is 5347.

MILITARY AERONAUTICS. The application to and in the military service, whether ashore or afloat, of any device or apparatus intended (a) to carry passengers and war material from one point to another in the air, for purposes of observation or of destruction or both, and (b) to rise and remain in the air, at an altitude controllable within limits, for purposes of observation. Hence there must be considered, balloons, captive and free; kites (see under KITE; MILITARY OR MAN-RAISING KITE); dirigibles; aéroplanes; and organization and training of air service.

BALLOONS

Captive Balloons. The balloon was first used in war, and by the French, at the battle of Fleurus, June 26, 1794. This balloon, a captive one named the *Entrepreneur*, was mounted by Charles Coutelle, and was of material benefit to the French General Jourdan by informing him as to the movements of the enemy. This same balloon was later used in the defense of Maaubeuge, and in the sieges of Charleroi and Mayence, 1796.

No balloons were employed during the wars of the Empire. The French sent up one in 1859 before Peschiera; balloons were used during the American Civil War and by the United States troops in Cuba in 1898 before Santiago, where they proved not only a failure in respect of the acquisition of information, but a source of positive danger by giving the Spaniards the exact range. Since the development of the dirigible and the invention of the aéroplane spherical ballooning, whether free or captive, has diminished in interest and value. This is, however, not to say that it has become obsolete. For example, the French army in 1914 made use of *auxiliary* balloons (320 cubic meters) for colonial expeditions; of the so-called *normal* balloons (500 cubic meters), captive, for field service; of *siege* balloons (750 cubic meters) equipped with a ballonet; and of *ballons de place* (fortress balloons) 980 and 1600 cubic meters respectively,

for free ascensions. All of these are inflated with hydrogen, save the 1600 cubic meter, which uses coal gas.

Spherical balloons are to-day *paneled*; i. e., whereas formerly the seams followed the meridians of the surface, they now in addition are sewed along seams parallel to the equator. This has the effect of limiting a tear, should one develop. Captive balloons are usually made of double vulcanized cloth, and thus do not require varnishing, besides being stronger, more impervious and more durable. To preserve the India rubber from the effects of the sun, balloons are painted with lead chromate, thus producing a characteristic yellow color.

Kite Balloons. The spherical captive balloon is open to some very serious objections: it offers a poor resistance to wind squalls; in a wind of 8 to 12 meters per second observation becomes difficult, and beyond 12 meters impossible. A German officer, Von Parseval, therefore conceived the idea of constructing a balloon which should at the same time be a kite, the so-called *Drachballon*, or kite balloon. The stability of this balloon would increase as the wind rose and the only limit to its possibilities in this respect would be the strength of the materials used. It consists of a long cylindrical part closed at each end by a spherical cap. At the rear is attached a rudder of toric form, carrying at its

KITE BALLOON.

forward end an air-admission funnel and at the other a vent. In the interior of the balloon proper is situated a ballonet, whose function is to preserve the invariability of form of the system, and into which air is admitted by a funnel and valve. The tail of the kite consists of a series of reversed parachutes opened by the wind. To a sort of belt parallel to the axis of the cylinder are attached, forward, the bridles, which themselves work down to the main retaining cable. No net is used in this type of balloon; the car is suspended from bridles fixed to the rear.

As soon as the balloon is released it orients itself so that its main axis lies in the plane of the wind; this axis, moreover, is so inclined as to cause the nose of the balloon to lift. The wind now enters the rudder by the admission funnel; the rudder, inflated and assisted by the parachutes, fixes the orientation of the balloon. At the same time air begins to fill the balloon by the funnel, escape being prevented by a check valve. When the interior pressure becomes too great, relief is afforded by the escape of air into the rudder through the ballonet valve. The filling sleeve is always kept closed. Finally, should the pressure of the gas in the balloon exceed a certain limit, the interior wall of the ballonet bears upon the envelope of the balloon proper so that the latter pulls a cord communicating with the gas valve and automatically causes the latter to open. All danger of bursting by excess of pressure is thus eliminated. The supporting

effort of the balloon is increased by the effect of the wind on the rectangular lateral wings; these serve further to diminish the inclination of the balloon as the wind rises.

This balloon is the regulation captive balloon of the German and Austrian armies. If we are to believe the French, it is not after all superior to the French siege balloon; it ascends to a lower altitude for the same length of cable un-wound: it is difficult to transport and to operate. However, in open country and on good roads, the Parseval even while up in the air can be transported from one point to another of a field, even at a trot. A small balloon (100 cubic meters) of this type has been used in France to carry the antennæ of the field wireless system. It may also serve to carry a photographic camera.

Use of Captive Balloons. Captive balloons may be employed to observe the movements and positions of the enemy and to guide indirect artillery fire. Reports are usually made by telephone. Conventional signals are also employed. In average country an altitude of 500 meters permits a reverse view of deflated positions and, if the weather be clear, of observations as far as 7 kilometers. Before and during a battle an observer in a captive balloon may check the reports of cavalry reconnoissance, pick up reserves, make out field works, etc. During sieges captive balloons might be very useful. At night they may be used for the transmission of luminous signals as far as 30 kilometers. But after all is said and done, their use has always been limited: fog, rain, snow, would prevent observation and they are exceedingly vulnerable to artillery fire; if attacked, the only means of safety is to descend at once as rapidly as possible.

Naturally the possibilities of the captive balloon have led to the organization of balloon service and of balloon troops. As a rule, these troops belong to the Engineers, and are charged with the care, maintenance, and use of the material. Apart from the balloon proper and its equipment, the material includes vehicles for transport, trucks for ascensions, apparatus for generating hydrogen gas, and the necessary supplies, tools, etc., and is usually assembled and kept in balloon parks. These are stationed in the great fortresses, while the general administration, instruction of officers and men is managed by a central establishment. The train accompanying a captive balloon in the field is considerable, including the reel wagon with its tender, a tool wagon, tube wagons carrying compressed hydrogen, and wagons for the balloon equipment proper.

The siege-balloon train is somewhat smaller, but one of its wagons carries photographic equipment.

Free Balloons. Free balloons have no value in military operations save as a means of communication or of escape from besieged places. The Austrians, however, in 1848, made an attempt to use them to bombard Venice, but failed because the wind drove them off. At the siege of Paris, in 1870-71, between September 23 and January 28, 64 free balloons were sent out. These carried out about 2,500,000 letters and 358 carrier pigeons, of which 56 returned to the besieged city. Of the 64 balloons, 2 fell into the sea, 7 into the hands of the enemy, 12 others were captured, but their crews managed to escape.

DIRIGIBLES

The modern dirigible balloon owes its origin to the efforts of two French officers, Renard and Krebs, of the Engineer Corps, who, experimenting in 1884 and 1885, constructed a balloon, *La France*, 50.4 meters long and 8.4 meters in diameter, driven by a propeller actuated by an electric motor. A speed of 6.5 meters per second was attained, and under favorable conditions of wind and weather this balloon made trips, modest to be sure, but significant of greater progress. Since the work of the French officers, as is discussed under AERONAUTICS, there have been important developments of the dirigible, but all things considered, so far as practical value is concerned, it is almost useless save for military purposes, and even in war its application and possibilities are limited.

Types. Three types of dirigibles are found in the military service. The semirigid and non-rigid are thought to be in many respects greatly superior to the rigid. Their chief advantage consists in the ease with which they can be taken apart and assembled, and in the fact that they can be transported deflated. The keel alone of the semirigid, however, calls for several freight cars, while the Parseval, a nonrigid dirigible, e.g., can be completely loaded on two. On the other hand, if the envelope should be torn, the semirigid and the nonrigid are put out of commission. To the usual classification into rigid, semirigid, and nonrigid some objection has been raised. In the first place the term "semirigid" is in itself improper, inasmuch as the balloon itself is collapsible, but uses a rigid member or frame to connect the car and its accessories with a gas bag. A more rational classification, according to French authorities, from the military point of view, would seem to rest on volume as the determining factor. We thus have:

Vedettes: 2000-4000 cubic meters and taking up three aeronauts. Limited radius of action; to accompany field armies and remain as close as possible to the enemy; easy to handle and to transport; rapidly inflated; no special hangars needed.

Scouts: 6000-7000 cubic meters. Capable of remaining up a considerable time and of going far; of special value when hostile armies are making their approach marches; special hangars needed.

Cruisers: "aërial dreadnoughts," exceeding 10,000 cubic meters; able to go far and remain up a long time, and thus available for strategic reconnoissance; to be concentrated near frontier and ready to start at the first signal; special hangars needed.

But this classification is almost completely robbed of any value by a brief consideration of the requirements a military dirigible must satisfy. In order to be safe from hostile fire a dirigible must rise to a considerable altitude. This altitude is at least 1500 meters, and will increase as balloon artillery improves. Moreover, since it is important that a dirigible shall pass as little time as possible in friendly territory, it must reach this minimum altitude as rapidly as possible and there maintain itself during the greater part of its journey. Hence the condition imposed upon dirigible builders of furnishing a machine that will stay up for a considerable number of hours and remain for at least two-thirds of the time at an altitude of at least 1500 meters. An airship failing to satisfy these

conditions would have very little military value. In order to control rising there must be ballast; if, further, long voyages are contemplated, the supply of ballast must be increased; we thus necessarily arrive at the conclusion that the military dirigible must be of great volume.

The present tendency is towards the construction of the dreadnought class. In illustration of the progress made we may compare the German M I of 1912, of 6000 cubic meters, equipped with two motors of 75 horse power each, developing a speed of 45 kilometers an hour, and having two propellers, with the Z VIII, built in 1914, of 22,000 cubic meters, having three motors of 180 horse power each and four propellers. The Zeppelins actually built on Jan. 1, 1914, with 540 horse power, developed a speed of 77 kilometers an hour. The comparison is still more striking in France. Thus, the Ville de Paris, of 1906, of 3200 cubic meters, speed 43.2 kilometers an hour, developed by one 70-horse-power motor, and with one propeller, is plainly obsolete when compared with Astra XVI, of 23,000 cubic meters and a speed of 90 to 100 kilometers an hour, developed by four 250-horse-power motors actuating four propellers.

So rapid has been the evolution of airship design that dirigibles built before 1910 by the time of the European War which began in 1914 were quite obsolete. In the development of actual type most nations were content to follow models of French or of German origin. In the construction of some of their ships, however, the Italians even before the European War exhibited originality by inclosing the stiffening member or frame in the gas bag itself. This frame is not rigid, but composed of articulated panels, thus accommodating itself to the variations of form of the envelope. The car of the P class (containing dirigibles of smallest volume) is of steel and water-tight, so that in case of need it may float on the surface of the water. In the M class (M = mean, between the smallest class, P, and the largest, G) the car is of steel and completely closed, and thus shelters the crew from wind and weather and at high altitudes. These are real military qualities, for they permit the balloon to go out under unfavorable climatic and weather conditions. In the G class the car forms an integral part of the balloon body. A later type was a crewless dirigible operated by Hertzian waves. These work one propeller forward and two aft, and a fourth, of vertical axis, under the car and thus helping the dirigible to rise. It was said that the trials of this dirigible in July, 1913, turned out very well. We give below, illustrating type, equipment, speed, etc., lists of the war dirigibles of Germany and of France respectively. The latter contains only the airships recognized by the French as having any military value. The tables giving the published state of affairs as it existed early in 1914 just before the war are taken from Rasch and Hornel's *Taschenbuch der Luftflotten* for 1914, though some differences, occasionally quite marked, will be noticed when such information is compared with French authorities.

On Jan. 1, 1914, the military airship (army and navy) fleets of the world were as shown in table at top of page; and to these must be added a certain number of commercial and experimental ships, of which on Jan. 1, 1914, Germany had nine (one building), France two, Italy three, Japan one, Austria two. Germany excepted, none of these has any military value.

There is reason to believe that the number of military dirigibles in existence at the outbreak of the European War was considerably greater than the number published, and during

the progress of the war new dirigibles were built and placed in commission, while others were destroyed. It is reported that L I, L II, L III, L IV, and L VIII have all been destroyed, wrecked, or lost.

Employment of the Dirigible. Dirigibles may be used in two ways: (1) in the acquisition of information; (2) in the infliction of damage upon the enemy. Certain general conditions affect both uses. The dirigible must be equipped with means of communicating with its own side. So long as it remains within the working range of telescopes or field glasses it may use visual signals; when beyond this range it must have recourse to wireless telegraphy. Since a dirigible is liable to attack by other dirigibles or by aeroplanes, it must carry rapid-fire or machine guns to beat off such attacks. By reason of its very nature the dirigible must have a "port" or base, at which are found the hangars for housing the dirigible when not on service, machine and repair shops, gas generators, in short all the apparatus and tools for use and maintenance.

Information. Bearing in mind the constitution of airship fleets, the nature of the duty will depend on the volume of the dirigible. The smaller airships naturally will be useful for tactical reconnoissances, e.g., to report on armies executing their marches of approach; they may conceivably be employed even when armies are in actual hostile contact. The value of such reconnoissance will naturally depend on the rapidity with which the information obtained may be transmitted to the headquarters interested. Obviously wireless telegraphy is here indicated. Communication by this means over a range of 300 miles and more is an accomplished fact. On the actual field of battle accurate information may be sent of the emplacement of the hostile batteries—information of the greatest value and importance—as well as of the general situation of the enemy. This sort of work, however, falls more naturally to the aeroplane, as indeed will probably be found the case with all close work.

Dreadnoughts, the "battleships" and "battle cruisers" of the air, would be used on what is known in the military profession as "strategic reconnoissance," i.e., on long journeys into the heart even of the enemy country, for the purpose of detecting the concentration of troops and the direction of great movements. This function calls for the installation during peace of stations near the frontier, from which without loss of

time dirigibles may proceed into hostile territory. Such stations were found along both sides of the Franco-German frontier, in the great fortified positions, e.g., Metz, Strassburg, Verdun.

Offensive Employment of the Dirigible. Even before the war military authorities expected no great results from bomb throwing and this opinion has been sustained. This must not be understood to mean that such results are impossible or even improbable. With improved apparatus for releasing the bomb or projectile, with more experienced operators, it is possible that success will be attained. It appears to be true that at altitudes safe for the dirigible the expectation of hits is slight; at lower altitudes the dirigible would probably be destroyed before

affairs, so far as made known, and the experience of the European War, that the dirigible has been a disappointment to its partisans. Offensively its performance would seem to have been negligible; whether it achieved in reconnaissance results more tangible is not as yet known.

Defects of the Dirigible. The dirigible is open to some objections, the chief of which may be summed up in one word—bulk. A corollary is its inability to operate by day through fear of hostile aeroplanes. The first cost of a military dirigible of the dreadnought class is great—in the neighborhood of \$500,000. Compared with other items of the military budget, this is not in itself a large sum. But it is large compared with the cost of an aeroplane

* Previous to war.

achieving any useful purpose. Since the supply of really destructive ammunition that may be carried along is limited, the possibilities of destructive effect are limited. If the attack fail, the journey of the dirigible is worse than useless, and in any case its ammunition once exhausted, it must return to its home port in order to replenish. It is conceivable of course that a government disposing of a fleet of say 25 or 30 dirigibles may send it to hover over an army, or the capital, or a great fortress, over dockyards and arsenals, in the hope of sending down so many projectiles, incendiary and others, that some of them will strike the target. But, as before remarked, if the fleet remain at a safe height, its own fire is uncertain; if it descend so low as to assure a reasonable expectation of hits, it exposes itself to the high angle fire of the defense. It would seem from the state of

—\$12,000 to \$15,000—when it is considered that both machines have similar functions. If a remedy be sought in the construction of smaller dirigibles, we must realize that, although the first cost is much reduced, nevertheless a large sum has been spent to build an instrument whose work can be as well done, if not better done, by a much less expensive machine, the aeroplane. In fact, as the dirigible diminishes in volume its functions tend more and more to coincide with those of the aeroplane. In particular its offensive powers, varying as these do with carrying capacity, tend to disappear, or at least to reach so low a point as to be more than compensated by the superior advantages of the aeroplane, in respect of reconnaissance. Accepting, then, the fact that the dirigible must be of great volume, it is clear that its plant must be of vast size and correspondingly costly. A dirigible in

a fixed shed is a prisoner until the wind is favorable to its issue. The objection is removed, however, by constructing a revolving hangar, such as those built by the Siemens-Schuckert firm in Germany at Biesdorf. This opens at both ends, and may turn 90° either to the right or to the left. It is even proposed to construct subterranean or semisubterranean hangars, into which the ship would be allowed to sink, and then be closed in by a trap-door roof. The cost of these installations would evidently form a serious item in the military budget.

On the outbreak of war the fleet would of

be sheltered, is at the mercy of the wind. But as yet no dirigible has been built which is able to "keep the air," not to say indefinitely, but for a relatively long time, a week or two weeks, without landing. It must return to its own or to some other base or make a landing in order to renew supplies. It is a fact that some dirigibles may remain up 30 hours and longer, and it is certain that this duration allows an ample margin of time for action. But it is also a fact that, from its bulk, the dirigible is vulnerable, far more vulnerable than the aeroplane.

course use the stations established during peace on or near the frontier. If these, however, should be destroyed, or if an invasion should be made into the heart of a country, then, if dirigibles are to accompany the army, either a dismountable plant must be provided as a part of the train or the ship must return to a far-distant base. The transportation of such a plant would be a serious matter; the absence of the ship might involve a military disadvantage. The transportable mooring mast of the English army furnishes a sort of solution, but so far as known it is used for only very small models. A dirigible that has landed in the open, if it cannot

The maximum ordinate of the trajectory of the 6.5 centimeter Düsseldorf gun is given as 7900 meters, that of the 10.5 centimeter as 8300 meters. To say nothing of the present impossibility of a dirigible's rising to such a height (the altitude record for dirigibles is 3300 meters) it is clear that long before reaching it its usefulness both in offense and reconnaissance would be very seriously diminished if not completely destroyed. The dirigible is further seriously exposed to aeroplane attack, against which it might prove helpless, unless escorted by its own combat aeroplanes. The value of the dirigible is greatly reduced at night; at useful alti-

tudes its bulk in clear weather should be easily discernible, where an aeroplane would be practically invisible. Again, the proper speed of a dirigible must exceed by 4 or 5 meters that of any wind it may have to meet; a speed of 20 meters would allow a dirigible to proceed on 85 days out of 100, one of 12 meters on 40 out of 100. If we diminish these numbers on account of rain, snow, or fog, and take into account gas leakage, it is clear that the usefulness of the dirigible would be still further reduced. Obviously some of the objections cited will lie also against the aeroplane, but in a lesser degree, because of lower cost, greater ease of handling, comparative invulnerability, and ability to profit by fleeting opportunities not within the grasp of its bulky rival. Lastly and in general, the dirigible must for the present be regarded as a more or less delicate machine, exposed to danger from fire, e.g., from the blast of its own guns, weather, and the unforeseen causes of disaster.

Advantages of the Dirigible. The dirigible is superior to the aeroplane in that it affords a better gun platform, can carry heavier guns, can navigate by night, remain in the air a much longer time, and carry a much greater useful weight. Its wireless equipment has a much longer range. In gun practice some notable results have been attained; e.g., the German Z V at Döberitz early in 1914 made hits on a target 12 by 3 feet at a range of over 1800 yards. In yet other trials a 2-inch gun at an elevation of 2000 feet scored bull's-eyes on a target 30 by 15 feet suspended 1000 feet in the air from a kite balloon; this gun was mounted on top of the gas bag. Z VIII ascended on March 29, 1914, to a height of 10,000 feet, and, as a further example of the possibilities of the dirigible, L III (since reported lost in 1915), after a trip of 35 hours at 62 miles per hour, had enough fuel left for a journey of 16 hours more. This airship carried a searchlight of 40,000 candle power.

AÉROPLANES

That motor flying should have made a special appeal to the military profession was perfectly logical; sporting apart, no real use for flying has so far been imagined comparable with that of the service of reconnoissance in war. In 1909, at the Rheims meeting, the first real tests of aeroplanes from a military point of view so impressed the French government that it ordered several Wright machines for military use. It was at this meeting that the Gnome motor first appeared. In 1910 we find the French using aeroplanes (and dirigibles) at the fall manoeuvres held in Picardy, with results so satisfactory as to lead to the prediction that the whole service of reconnoissance would be revolutionized.

The progress of military flying was still further strikingly displayed at another notable aviation meet held at Rheims in the following year, and at the Paris Aeroplane Salon, which marked the close of the aeronautical season of 1911. The machines shown indicated that at least an approximate solution had been reached of the various problems of military flying. The engines were more powerful; an improvement had been made in the landing chassis in respect of both strength and simplicity. The single-seat, high-speed monoplane attracted very serious attention; indeed it may be said that this machine

emerged approximately as a distinct and important type. Capable of reaching a speed of 80 miles an hour, it was recognized that a most valuable instrument of reconnoissance had been created, limited, to be sure, in its purpose, but that purpose possibly of the most vital importance.

In the development of military aeroplanes France early took and maintained the lead. In 1912 she appropriated nearly \$5,000,000 to military flying, an amount increased by a popular subscription of \$500,000. Germany, wedded to the dirigible, and at first regarding flying as of limited value, nevertheless took alarm after the French manoeuvres of 1910, and with characteristic thoroughness set to work to build machines and to develop and train military flyers. In 1912 she appropriated over \$3,000,000 for this element of her war power, and increased the amount to \$10,000,000 in the budget of 1913. Russia followed suit and her aerial budget in 1911 was \$5,000,000. Austria, Japan, Italy, and Spain then took up the subject. England was far slower; it was not until 1912 that she gave it serious consideration. What was expended by the combatant nations in connection with the great war is of course only a matter of conjecture until the publication of the detailed budgets. In the meantime it is reported that orders to the value of \$16,000,000 have been placed in the United States by European nations at war, for aeroplanes and motors.

Use of the Aeroplane in War. Like the dirigible, the aeroplane has two functions in warfare—reconnoissance, involving the acquisition and transmission of intelligence, and attack, the infliction of damage upon the *matériel* and *personnel* of the enemy. Of these reconnoissance far outweighs the other in importance and value. The applicability of the aeroplane to the business of collecting information has been almost self-demonstrated from the start; its usefulness as an engine of destruction remains on the whole undeveloped. Other uses have suggested themselves during the course of the war. Daily communication between Przemysl and the Austrian lines seems to have been maintained by aeroplane. Russian aviators have been employed to bring up ammunition from the distant rear. These cases, however, are special.

Information. Air craft, i.e., dirigibles and aeroplanes, have no effect on strategy, the principles of which are declared to be immutable. But having in view the hugeness of modern armies, preliminary strategical operations must to-day be carefully considered; the strategical plan once adopted, air craft may serve to accelerate the passage to the tactical phases of the situation. This effect can never be great, however, since it is to the interest of any army to reach the tactical phases without loss of time. It is therefore in the domain of tactics that we must seek the influence of air craft. This statement almost shuts us up to a consideration of the aeroplane alone. The dirigible conceivably is superior in strategical reconnoissance, because of its ability to keep in the air longer than its winged rival, and especially because it is better adapted to navigate by night; but in tactical reconnoissance, in the observation of troops after they have left the roads, after they have taken up the formations leading to combat, the dirigible must take second place.

In its simplest terms the military problem to be solved by a military aviator consists in

knowing how to get the information wanted and to transmit it to the headquarters interested; hence the military aviator must be able, in full flight, to read a map, must thoroughly understand the three arms, be acquainted with their

carried out by both infantry and cavalry, but chiefly by cavalry. Since each side is doing its best to conceal its own strength and purpose from the other, there results what is called the "fog of war," i.e., the uncertainty as to the im-

TYPES OF MILITARY AÉROPLANES

I. GERMANY *

DESCRIPTION	Length over all meters	Spread meters	Area of supporting surface square meters	Speed, kilometers per hour	Motor and horse power	Climbing power	Weight kilograms	Useful load, kilograms	Supply of fuel carried	Number of propellers and mode of mounting	Remarks

* French military aéroplanes, it was announced, should carry on the under side of each wing (lower wing in biplanes) a tricolor cockade one meter in diameter.

formations, and know how to follow a manoeuvre.

From the earliest time of mobilization, concentration, and advance of an enemy, each side to obtain information resorts to reconnaissance,

mediate purposes of the enemy and as to the means he employs to carry them out. In spite of all efforts the information brought in to headquarters may be untrustworthy, if only because it may be several hours old before it is received.

Hence it has been the business of military genius, other things equal, to pierce this fog of war and by the proper use of troops to beat the enemy.

The *aéroplane* has almost completely dissipated the fog of war. Long before an army comes up its strength and composition are known, its direction and rate of march disclosed, its purpose revealed. Suitable measures can therefore be taken in ample time, for doubt has given way to certainty, and a commanding general may act in full knowledge of the task before him.

So complete and accurate is the information possible by air scouting that enthusiasts have declared that the reconnaissance duty of cavalry has become obsolete. But to accept this view would be to fall into grave error. With two armies at grips, or about to come to grips, much remains to be done by the intimate, immediate, and local reconnaissance, both of the ground and of the enemy by the troops immediately interested; in other words, the *aéroplane* can never be made to feel the enemy. The *aéroplane* is of inestimable value in giving notice, as already said, of an impending attack, and even of the nature of the attack; the immediate dispositions however, must, as before, be left to the troops themselves.

To form a concrete idea of the service of reconnaissance possible to the *aéroplane*, a machine doing no more than 80 kilometers per hour may fly say 125 kilometers in advance (four days' march) and observe a strip from 8 to 10 kilometers wide. The information brought in, if the machine returns, will be only an hour or two old when received; with wireless, it would represent at the moment the exact military situation. Now this information, if sent in by cavalry patrols, may be 24 or 48 hours old. Moreover, cavalry can never report more than the "apparent contour," whereas the *aéroplane* looks down into the heart of things. It may do admirable service in the transmission of orders and for establishing contact between troops engaged. The opportunity for this presents itself when roads are choked with troops and guns, when telegraph and telephone lines are cut, and wireless ceases to operate.

Some idea of the importance of air service may be formed from the record of over 18,000 hours of flight, and distance of 1,800,000 kilometers by French aviators. The other combatants no doubt can furnish similar records.

Moreover, the *aéroplane* has directly intervened on the battle field itself. Thanks to the increased range and calibre of modern artillery, effects, sometimes surprise effects, are possible at distances undreamed of in elder days. The case may be even more generally stated: so powerful is the modern gun, whether the classic fieldpiece or the larger calibres brought into action in later years, that distant action may be said to be the rule. But in order to produce results the nature of the target and the range must be exactly known. Now, in obtaining these elements the *aéroplane* is of the greatest value, as appears when we recollect that modern fire is indirect, i.e., the batteries engaged do not see the target. Hence it has been found necessary for the captain of a battery to take his post at some point from which he could observe the fall of the projectiles and so correct his practice. The *aéroplane* to-day enables the battery to see; it indicates targets,

checks and corrects fire. Communication upward, from the commanding officer of the battery with the aviator, is easily established by means of visual signals. Communication downward is effected by dropping written indications suitably weighted within easy reach of the battery. - Doubtless improved methods will be adopted in time. See FIELD ARTILLERY.

More generally, the *aéroplane* reveals the extent of the position occupied by the enemy on the field, the number and position of his reserves; from its reports the general may decide whether a turning movement is possible or desirable, when the moment has arrived for a general offensive movement. According to one authority, "it may be and will be offensively used to bombard important points, such as hills, woods, river banks, bridges, etc. *Aéroplanes* equipped for offense will be held in reserve and sent out just before the assault to drop their projectiles upon these points in such volume that no troops could possibly remain in the position." The *aéroplane* may warn its own side of the dangers to which it is exposed from batteries whose presence within range would otherwise be unknown, and thus lead to the adoption of measures either to destroy the batteries or to seek protection from their fire. We cite a few instances from the present war. A single French aviator on Feb. 17, 1915, discovered 21 enemy batteries. Air reconnaissances in the Dardanelles succeeded in locating new gun positions in the forts, a line of surface mines, encampments, and permanent batteries. Aviators flying over the German lines in the La Bassée district picked up six batteries, which a few minutes later were being shelled by the French Artillery (February, 1915). The success of the British Artillery at Neuve Chapelle is in no small measure due to the air service. It has increased the effect of infantry fire; will probably be found of great assistance in coast defense, and lead to increased use of movements by night and to attempted concealment by day.

In reconnoitring the ground from an *aéroplane* telephotography has been found extremely useful. Not only may a terrain otherwise inaccessible thus be forced to reveal its nature, but the results of the reconnaissance are brought in long before an ordinary reconnaissance patrol could have set to work. Military features are presented in their relation to one another; by suitably projecting them upon a map distances may be accurately measured. Other valuable information may also be obtained, such, e.g., as the possibilities of a defensive position or the seriousness of the opposition to be expected at a given point from its physical configuration.

Photographic views may be obtained by the use of the ordinary camera with the telephoto lens, by a motion picture camera which presents a continuous view of the section over which the *aéroplane* or dirigible passes, or by the use of the phototopographic camera, invented by Capt. Scheimpflug of Vienna, Austria, by which a combination of lenses presents an accurate view of an area of 32 square miles if taken from an elevation of 3000 feet or of 126 square miles if taken from an elevation of 8000 feet.

Inasmuch as the *aéroplane* is above all things an instrument of reconnaissance, the question of communication with it, and of receiving information from it, while in flight, is of the first importance. Among all methods tried, obviously wireless telegraphy holds first place.

The installation of wireless on board an aeroplane in some respects is notably different from installation at a permanent station. No ground connection for the antennæ is possible, so a second aerial or "counterpoise" is employed to replace the ground. In the aeroplane two systems exist; in the first, a fine trailing or drop wire, almost a hundred feet long, is used as an antenna, and the counterpoise is formed by the fuselage and metallic parts; in the second, an aerial is permanently fixed to the aeroplane, and the counterpoise consists of a second antenna similar to the first. The first system is the better in respect of efficiency; but the trailing wire may be caught by objects on the ground in case of sudden descent, or in the propeller itself. This last disadvantage disappears of course in the tractor type of aeroplane. The permanent aerial set has one serious objection—its small range of communication, not over 10 or 12 miles. In the matter of apparatus the generator and transformer are greatly superior to the induction coil. On account of the noise of the motor it is easier to send messages from an aeroplane than to receive them on board. This difficulty however, will very likely be removed by the perfection of a device to shut out to a great extent the noise of the motor and at the same time to increase the strength of the received signals. It should be remembered, too, that it is far more important for an aviator to send than it is to receive.

Other means of communication are visual signals, such, e.g., as the Means smoke telegraph. This is an apparatus emitting long and short puffs of smoke as desired, thus producing visually the dots and dashes of the Morse telegraph code. A similar apparatus tested in France consists of a tube parallel to the main axis of the machine and so placed as to catch the blast of the propeller. To this tube is connected by a suitable valve a reservoir of lamp-black; by opening and shutting the valve long or short puffs may be produced, thus giving the Morse alphabet. Signals are visible at 10 miles. In Germany a lamp using an Edison accumulator has been invented showing green to starboard and red to port for 110 degrees, and white forward and aft. The current may also be used to light up the instruments on board; by introducing a keyboard signals may be made. Other visual methods are flashing lamps by night, between air craft in the air or between them and the ground. On dirigibles the semaphore may be used. Written messages of course may be dropped at prearranged points or where needed; parachutes may be used for this or messages may be merely weighted. A special apparatus for this class of communication is Fugairon's: a hollow cylinder carrying the message is fitted with a mercury-fulminate cap which on landing ignites a charge of Bengal fire and so attracts attention. This signal may be seen by day.

THE AEROPLANE AS AN ENGINE OF DESTRUCTION

The possibility of using the aeroplane to inflict damage upon the enemy has of course been a matter of discussion and experiment. Given a machine able to pass, if not to hover, over an enemy or his arsenals, dockyards, depots, etc., and itself apparently out of harm's way, the idea of using this machine to injure the enemy is alluring. And apparently nothing could be easier than to drop a bomb, whether

explosive or incendiary, upon the target; if the target be large enough, a miss would seem to be impossible. But a little reflection shows that the conditions under which an aeroplane must work militate against the success of its offensive effort. It must maintain a certain speed; any error in the evaluation of this speed destroys the accuracy of the fire. In order to be safe itself from hostile fire it must remain at a certain height, and at 1000 meters in the air infantry fire is still to be avoided. Now, the greater the altitude, the less accurate becomes the practice of the aeroplane. Moreover, projectiles dropped or launched from great altitudes may encounter air currents wholly different from those in which launched and thus be deflected from the target. This condition is general, defies correction, and is independent of the precision of the instrument used and of the skill of the operator. Its effect increases with the crudeness of the ammunition; i.e., pear-shaped bombs, even spherical projectiles, apart from their inherent inferiority to ogival projectiles, are more likely to be affected by the perturbations of the atmosphere than a projectile designed to stay on its intended trajectory. The uncertainty attendant upon the use of primitive ammunition is so great that we may regard this sort of fire as almost useless. A pear-shaped bomb, dropped or thrown from an aeroplane going at speed at a great altitude, will probably miss its target. The conditions laid down, so far, as affecting the precision of bomb dropping, naturally, other things being equal, apply to aimed fire from a suitable gun carried by an aeroplane.

Of a different sort is the limitation imposed by the nature of the machine itself—the impossibility of carrying explosives in any serious quantity. But this limitation may prove only temporary. An aeroplane able to carry 1000 pounds of explosive is entirely possible, and it is conceivable that a fleet of 20 such machines might do an immense amount of damage, even if only one of four projectiles should find the target. Much would depend upon the nature of the target; e.g., dockyards, dirigible sheds, reserve troops of all arms in mass or in bivouac, especially if surprised—all or any of these might suffer great damage under aeroplane attack, where troops entrenched might escape serious injury. If the target is able to defend itself, the aeroplane's chances of hitting are still further reduced. As is well known, the accuracy of gun fire from the surface of the ground is checked by observation of the fall of the shots. Such control would be extremely difficult if not impossible for an aeroplane. But it would not be impracticable in an attack delivered by an air fleet to cause one machine to expend ammunition in trial shots, under the observation of its companions, and so enable these, on receiving by signal or wireless the data used, to open fire with increased chances of success. And it is obviously always possible for a skillful and daring aviator by a well-placed bomb to destroy a gun, wreck a troop train, or stampede a cavalry regiment. But after all these results would be only local, almost negligible in the sum total of operations.

This is far from saying, however, that the offensive functions of the aeroplane may not be so developed as to constitute a valuable factor. British aviators were reported to have done considerable harm to one or two German air-

ship stations, and even to have made two attacks in force, employing fleets of 34 and 40 aéroplanes, upon the German emplacements and depots near Ostend, with the purpose especially of destroying naval equipment and so defeating offensive preparations directed against English shores and commerce. Other examples are the reported (March 4, 1915) destruction of the German powder works at Rottweil, and the raid of 18 aéroplanes, May 27, 1915, on the German chemical factory at Ludwigshafen. Clearly such actions, if successful, would not be local in their results. It must not be forgotten that the subject is still in its infancy, that experience is lacking, even with the War in Europe, and particularly that the service of the aéroplane in reconnaissance has thus far so outweighed its possibilities in offense that these remain as yet undeveloped.

The announcement in 1911 of the Michelin prize for bomb-throwing contests led to some investigations of the problem of launching. P. Charbonnier, president of the Experimental Commission of Havre, published in the *Revue d'Artillerie* for December, 1911, the "Ballistics of the Aéroplane," in which he gave for a spherical projectile the elements of the trajectory *in vacuo* as well as tables of fire for both a vacuum and air. In the same number of the review just cited appeared a description of an aiming device, or sight, to be used by an aéroplane in flight. In the 1912 competition for the Michelin prizes Mr. Riley Scott, an American ex-officer of artillery (U. S. M. A., 1900), won both prizes, the first of 25,000 francs to the competitor who should from a height of 800 meters place out of 15 shots the greatest number of projectiles inside of a rectangle 140 by 20 meters, and the second of 50,000 francs to the competitor who from a height of 200 should place out of a series of 15 shots the greatest number in a circle of 10 meters radius. In the first contest Scott landed 8 out of 15 projectiles; in the second, 12 out of 15. He used an Astra-Wright biplane, at a speed of nearly a mile a minute. This was a very remarkable performance; it established beyond peradventure the fact that projectiles may be successfully launched from an aéroplane in flight with a more than satisfactory expectation of hits.

Scott's apparatus consisted essentially of two parts—the aiming device and the launching mechanism. The aiming device carries a telescope swung in gimbals by means of two concentric rings. In the launching mechanism the projectile rests in a sling one end of which is fixed to a crossbar of the inner ring, the other is held in position by an electromagnet and bolt. On the passage of the current this end of the strap is released and the projectile launched. It is best to discharge projectiles in pairs, as the equilibrium of the aéroplane thus remains unaffected; if desired, however, the apparatus may be so adjusted as to carry and release only one projectile at a time. The projectiles Scott used were ogival, with conical base, from the vertex of which projected a rod with three flanges, resembling the feathers of an arrow, and intended to keep the shot on the trajectory. Scott's apparatus is equally well adapted to the dirigible, but as it is possible for a dirigible to come to a stop in air, a special form of apparatus has also been devised for dropping projectiles vertically downward. This consists of

a set of four tubes, each containing a projectile; the release is made by mechanical means.

Another apparatus (German) for launching bombs was Renaud's. Three discharge tubes, fixed at the vertices of an equilateral triangle, are mounted on a plate and receive the drop-shaped bombs; to these tubes are fitted covers containing a mechanism for holding the bomb in place. Each tube is worked by a pedal set in a board before the operator; by pressing on the proper pedal the corresponding tube is opened; upon disengaging the cover the discharging mechanism proper is set, and a fresh pressure on the pedal releases the bomb. It is claimed for the apparatus that it is safe, light, quickly assembled, and sure of action.

A special (English) projectile was held up by bolts fixed to the aéroplane frame and released by a hand lever. These bolts engage in the projectile in such a fashion as to constitute the safety device of the system; hence on release the projectile is automatically set to explode. The projectile has a tail rudder and carries the percussion apparatus in its nose. An aéroplane bomb developed in England, known as the Martin-Hale, could be hand dropped from an aéroplane or airship or fired from a spring gun. One variety of bomb carrying shrapnel had a total weight of 20 pounds. This includes an explosive charge of four pounds of trinitrotoluol and shrapnel consisting of 340 steel balls. Previous to dropping or firing the bomb the safety pin is withdrawn, and this leaves a tailpiece free to rotate under the action of the wind on the vanes.

Metal darts have appeared as weapons for discharge from the aéroplane. One of these, invented by a Frenchman named Guerre, was an incendiary arrow, 40 centimeters long, 8 centimeters in diameter, and weighing about one kilogram. It contains a reservoir holding about a quarter of a liter of gasoline, which is set on fire by the striking of the point; it is thus intended for the attack on hangars, supply depots, dirigibles, etc. Experiments made with this type seem to have been convincing, for it was reported that the French Minister of War had decided to supply these arrows to aéroplanes. Thanks to a safety device, they can be carried and handled with impunity. Other types are darts pure and simple, about 15 centimeters in diameter, made of steel, cannellured or flanged to keep them from tumbling. Dropped in showers from a considerable height it is conceivable that these darts might prove effective against troops or horses, but at best the results to be expected are aleatory.

The problem of aerial discharge will not be completely solved until certain difficulties inherent in the aéroplane itself shall have been overcome. For example, fuse setting may be a delicate operation aboard an aéroplane in flight. The nature of the fuse itself is an important matter; percussion fuses might be dangerous, especially in the case of a hard landing. One problem has already been solved. Since light projectiles are harmless, aéroplanes of special ascensional power have been built carrying projectiles weighing 100 pounds to 200 pounds and, according to French reports, successfully employed in May, 1915.

Armament of the Aéroplane. The question of arming an aéroplane with a machine or other gun presents itself under a twofold aspect. Material targets being here obviously out of

the question, such a gun would be used (a) against troops, (b) in combat against other air craft.

Against Troops.—No argument is needed to show that an opportunity, however fleeting, may present itself to an aviator to inflict considerable damage upon, e.g., a cavalry regiment, reserve troops in mass, or even upon a line engaged. But, as before remarked, such damage would be local and relatively unimportant. The real question turns on the possibility of so organizing aerial attack that a commanding general could send out a detachment or fleet of aeroplanes, just as he would a regiment or a brigade, to repel an attack or to make one itself. It would be rash to assert that an achievement of this sort were impossible; it is safer to say that unless aerial gunfire can be so organized it cannot be counted upon as a factor in the combat situation.

Combat between Air Craft.—The case is altered when we contemplate combat in the air between opposing aeroplanes and dirigibles. Here we may reasonably arm an aeroplane with a machine gun, such as the Lewis or the Benet-Mercie, in order to beat off or destroy a hostile aeroplane or to attack a dirigible. In fact, bearing in mind the great difficulty of reaching an aeroplane by fire from the surface of the ground, no other reasonably sure method presents itself of resisting a menacing aeroplane than to attack it with a machine of the same nature. To this end it must carry a suitable weapon and must expect to find its adversary similarly armed. A dirigible, to say nothing of the difference of bulk, owing to its slower flight and greater difficulty of manœuvring, would seem to be no match for an aeroplane carrying a machine gun and explosive projectiles. By remaining constantly above the level of the dirigible an aeroplane ought to be able to destroy it by bomb dropping; unless the dirigible itself carried guns upon its upper surface it could make no adequate answer to its smaller and more active antagonist. Apart from bombs, well-directed machine-gun fire delivered in the dirigible dead angles, if any exist, should put the airship out of commission. It is said, however, that the body of the dirigible has little to fear from machine-gun fire using small-arm ammunition. The 37-millimeter Hotchkiss is therefore mounted on some flying machines, and probably would prove effective. A totally different weapon is the Steinmetz "air-craft destroyer." This consists of a bomb at the end of a long wire let down just before the attack, which would consist in flying across and over the air craft to be destroyed, so as to cause the wire to bring up against it. As the flight continued the bomb would come in contact, "hook" itself in, and a suitable mechanism would cause it to explode. This device is recommended for the attack of dirigibles by night, and may even be used against hangars, depots, etc. The Germans, according to press reports, are dropping asphyxiating bombs from aeroplanes.

Upon the general subject of the tactics of air combat we must await the verdict of further experience. One point, however, would seem to be clear: since it is the business of an air scout to observe and report back, it would be his duty to avoid combat, just as a cavalry patrol may receive orders to avoid coming to blows with the enemy. Further, in future wars, aerial

fleets will strive for the "command of the air," as sea fleets now strive for that of the sea. Symbolical of this strife is the air battle, March 21, 1915, between Lörrach and Mülhausen, in which 20 aeroplanes were engaged on both sides. This is regarded as the greatest aerial battle since the beginning of the war.

If an early conclusion from the War in Europe be permissible, it would seem that the offensive effect of an air attack, so far as measured by the known general situation, has, in marked contrast with the reconnaissance effect, been without any specially significant results. Air scouting, in the west at least, soon produced a state of virtual siege between the contending armies. No effect in the least comparable with this apparently can be attributed to air combat. But this conclusion is advanced with hesitation, because official reports later may bring to light instances of air attack of the greatest importance to the combatants concerned, instances perhaps immediately local, but attended with the greatest consequences.

The Attack of Air Craft.—With the development of air craft, whether dirigible or aeroplane, has come the development of weapons for their attack. Obviously the conditions are difficult. The target moves at high speed and the opportunities of aiming and firing are fleeting. The possibility afforded, in firing at a land target, of correcting for subsequent shots by observing the fall of the projectile, does not exist in firing at a target in the air, certainly not to the same degree. All ordinary weapons, the fieldpiece, the howitzer, the rifle, are well-nigh useless against air craft. The fieldpiece cannot be elevated, the howitzer fires (comparatively) slowly and its trajectory is curved. Both lack the facility of turning in azimuth, and the nature of the projectile used by them makes the observation of fire difficult. Rifle fire and machine-gun fire lack range; they might probably inflict no serious damage, even if the target were hit, and observation of results is practically impossible. Hence the necessity of providing special rapid-fire guns for the attack of air craft. These must have an all-around field of fire, be susceptible of elevating to at least 70 degrees, and admit of rapid changes of aim. Special ammunition must be provided, suited to the target and permitting the observation of the projectile during its flight. The fire itself must be carried on in a special manner. Ranging shots being out of the question, the only course is to use sweeping fire, based on the estimated or measured distance.

The calibre of balloon artillery depends on the conditions of service and varies from 3.7 centimeters to 12 centimeters. In a tactical point of view, i.e., to repel or destroy air craft threatening an army, whether by reconnaissance or by attack, great mobility is required. Hence the necessity of automobile mounts.

Various gun makers have addressed themselves to the business of making balloon-attack artillery intended to accompany an army in the field, to be mounted on shipboard and to be emplaced in coast fortifications. The guns manufactured by the Krupp are shown in the accompanying table, taken from Rasch and Hormel's *Taschenbuch der Luftflotte*, 1914.

The Rheinische Metallwaren- und Maschinenfabrik of Düsseldorf constructed 5-centimeter pieces on automobile mounts of two types—fully armored and half armored—besides other cali-

MILITARY AERONAUTICS

1. BRITISH HYDROPLANE. A Type Developed for the British Navy in the War.
2. GERMAN NAVY CENTRE-FLOAT ALBATROSS SEAPLANE. A Type Used in the War in Co-operation with Zeppelins for Coast Raids and Harassing Shipping.
3. BURGESS-DUNNE SEAPLANE.

MILITARY AERONAUTICS

TYPICAL WAR AÉROPLANES MOUNTING MACHINE GUNS

1. BURGESS (AMERICAN) WAR PLANE, mounting Benét-Mercié automatic rifle on swinging crane giving 200 degree arc of fire.
2. ARMORED DEPERDUSSIN (FRENCH) MONOPLANE, with aéro-mitrailleuse.
3. FRENCH ARMY SPECIAL TYPE ARMORED AÉROPLANE, OR AVION, OF 1914, with Hotchkiss machine gun.
4. FRENCH ARMED AND ARMORED AÉROPLANE, machines assembled in 1914 to defend Paris from attack by Zeppelins. This is a Henri Farman biplane.

bres ranging from 6.5 centimeters to 10.5 centimeters. The 6.5 had an automobile mount, as also the 7.5 half armored; another 7.5 had a field carriage, so constructed as to admit of elevation to 70 degrees and of depression to 5 degrees. The 10.5-centimeter had a so-called "firing carriage." At maximum elevation, the 5-centimeter will send their projectiles to a height of 3720 meters, the 6.5 to one of 7900

The smoke shrapnel carries a head filled with smoke composition; this leaves a visible track of smoke from the point of burst on, and to a certain extent thus permits of the correction of fire. The balloon shell carries a detonating charge, and behind this, smoke composition. At 250 meters before the intended point of burst smoke begins to issue and continues the same distance beyond this point. If in the meantime

Average speed per hour	45 kilometers
Greatest speed per hour	60 kilometers
Climbing power, slopes of	1:5

mount, the Armstrongs one of 15.2 centimeter calibre. The (French) Deport air-craft gun can traverse 45 degrees on its carriage. Its trail is divided along its length, and the parts can be moved to the right and left respectively when in action.

The Krupp balloon projectile is a double-chambered shell; the forward chamber carries the bursting charge, the rear chamber a smoke-producing composition. Should a hit be made, a suitable fuse operates to detonate the charge. The smoke composition burns during flight and emits smoke from apertures in the wall of the shell. The flight of the projectile may thus be followed and corrections made. The fuse is extraordinarily sensitive; it must act on meeting the slightest resistance, and yet be safe in the bore of the gun and during flight. The Düsseldorf company already mentioned supplied three types of projectiles for balloon attack—a *brisant* shrapnel, a smoke shrapnel, and a balloon shell. In the first of these a suitable charge drives forward the bullets and the head of the projectile. This head has its own bursting charge, intended to act about 125 meters ahead of the bullets. Should the head strike before bursting, a suitable fuse causes it to burst on impact. While the bullets go forward several hundred meters in a sharp cone of 12 to 14 degrees, the head sends its splinters with great violence, two or three hundred meters up, down, right and left, in a broad cone of 200 degrees.

the shell should have failed to hit, a time fuse is set in operation and produces detonation; should this occur near the target, the flying fragments may hit and cause damage. The possibility of "mining" the air above fortifications against air-craft attack has been suggested. This plan would consist of sending up each evening a large number of small captive balloons to different heights to detonate either by judgment or on contact, each carrying a sufficient quantity of explosive to destroy any aeroplane or dirigible with which it might come in contact. These balloons may be supplemented by kites provided with long tails of malleable iron designed to foul the propellers of any air craft.

TYPES OF AEROPLANE

The division into monoplane and biplane does not of itself furnish a basis of military classification. Furthermore, whatever the basis, machines differ so much from one another in respect of form, size, and materials of construction as for the present to rob classification of any special usefulness. This question of type is not purely academic; apart from the importance of determining what type is best suited to the military service and what modifications it must undergo in order to adapt itself to varying conditions, it is clear that unity of type would greatly simplify repairs and replacements and the instruction and training of aviators. A step in the right direction would be so far as possible to adopt a standard system of control mechanism. So important is unity of type regarded by some authorities that it is asserted that 100 mediocre machines absolutely alike are better (in the military service) than 100 different models, however admirable each may be.

Since the sustaining power of an aeroplane varies with the square of its velocity, it is natural and logical that every effort should have been made to increase the velocity of its flight. Under these conditions the pilot's chief duty is to attend to his machine; it is therefore conceivable that his observations may be imperfect or inaccurate. As the aeroplane is above all other things an instrument of reconnoissance,

the military machine should therefore in the general case be at least two-seated—should carry an observer and a pilot. Further, since it is in the highest degree desirable if not essential that an observer should transmit his observations to headquarters as rapidly as possible, and without returning to his point of departure, we have to consider the possibility of adding still a third passenger charged with the dispatch of intelligence by wireless telegraphy or otherwise; and if, lastly, the *aéroplane* be offensively equipped, a fourth passenger must be taken on board to serve the gun or other engine of destruction. These conditions point to an *aéroplane* of great sustaining power.

On the other hand, the military situation may call for immediate information of a special character about a particular point. There is no question of destruction or of mapping but of special reconnaissance, e.g., the assistance of cavalry, the detection of hostile batteries, or the control of the fire of one's own batteries. What is needed is a trustworthy report by a trained observer, sent in or brought back with the utmost dispatch. Hence the one-seat machine, light, easily transported, driven preferably by a staff officer attached to headquarters. It may be found that for one class of duties the biplane, for the other the monoplane, is the better suited; but this is a matter to be determined by experience and one that in a military point of view does not necessarily affect the question of type. So far apparently we may recognize the high-speed machine, of small supporting surface, and a slower machine for duty, in which weight, rather than speed, is the feature to be considered; i.e., more specifically, we have the armored monoplane for cavalry and artillery reconnaissance, minimum speed 120 kilometers per hour; the armored biplane for general staff work, minimum speed 100 kilometers per hour; the armored biplane for purely offensive work, minimum speed 120 kilometers per hour; and finally, the large multiple-seated for special service requiring the coöperation of several passengers. In the United States the biplane has been favored for military purposes. As a matter of fact, all sorts of machines were and are found in the *aéroplane* fleets of the great military nations.

The conditions of the field-artillery service seem to require that *aéroplanes* should be permanently attached to this arm. In other words, the artillery feels that it should be emancipated from the necessity of calling upon the commanding general for *aéroplanes* when needed; that it should, on the contrary, possess and control its own machines, to be sent up at once when needed. And just as the needs of the military service call for the special assignment of flying machines, so should these, on account of the special duty they are called upon to perform, satisfy certain conditions.

In France the justice of the demands of the field artillery would seem to have been recognized; the plans for 1915 provided for the assignment of 20 squadrons (*escadrilles*) to assist the artillery. Similarly 10 squadrons were to be attached to the cavalry; provisional squadrons were indeed organized in 1914. A typical fighting biplane is the Vickers, designed for weight carrying and having a speed of 40 to 70 miles per hour. It is of the pusher type, built almost entirely of steel, and carries a small Vickers automatic gun covered in front by a hemispherical shield mounted on the barrel and

moving with it; this shield has mica windows. The muzzle of the gun projects through the nose of the fuselage, which is entirely covered in. The arc of fire forward is 30 degrees on each side of the line of flight. Another English military machine is the "Mark R. E." (reconnaissance—experimental), said to be automatically stable, of the tractor type, and propelled by a four-bladed screw driven by a 120-horse-power Beardmore-Austro-Daimler motor. A French mount is the Loiseau for a Hotchkiss rapid-fire gun, on a support high enough to allow fire over the tractor even with considerable depression. The gun is protected by a 4-millimeter shield in front; although the gunner is partly covered by this arrangement, he is nevertheless seriously exposed. From a purely military point of view this mount is regarded as meeting the objections to the tractor type of *aéroplane*.

Nearly all military *aéroplanes* are of the tractor type, i.e., have the propeller, generally two-bladed, in front. The machine is thus pulled, not pushed, through the air. This special form of mounting is safer for the aviator, who in case of accident falls above the weights rather than under them. It has the disadvantage of limiting the field of fire forward.

The war machine has an inclosed body, or fuselage; this, however, is not necessarily a military feature. The Russian biplane "Rusaki Wijas" (1913-14) carried a deck house, affording complete shelter to the crew. The armored *aéroplane* was seen during the war in such examples as the French Dorand biplane (1914), the Nieuport monoplane (1914), and the Voisin biplane. The fuselage of the Dorand carried steel armor 2.5 millimeters thick, said to be proof against rifle fire beyond 750 meters, and in many models the armor protection covered the pilot, observer, provisions, instruments, and especially the propelling mechanism. It may be remarked that all machines not aggressive were fitted with wireless. Multiple screws are the exception; the vast majority of *aéroplanes* are single-screwed. One form of the Dorand armored biplane has twin screws, and so have the Nieuport, Dunne, and Savary biplanes; the Russian Sikorski biplane carries four screws in front, driven by four Argus motors of 100 horse power each. This *aéroplane* has a supporting surface of 125 square meters, with a speed of 28.20 meters and a length fore and aft of 20.20 meters—an indication perhaps of the enormous increase in size and power to be expected in the future. If very long, continuous flights are attempted, special tanks are provided for the gasoline carried, as in the Farman biplane (1914), supplied for a 24-hour flight. All *aéroplanes* of course carry instruments; among these are found an inclinometer, to give the angle of incidence of the machine, a clock, an aneroid barometer to measure the height, a speedometer, and a tachometer to give the revolutions per minute of the motor. In addition some good form of compass must be carried, as well as maps in a map case. These instruments, as need hardly be mentioned, are not peculiar to the military machine.

To mark the progress made in the evolution of the military *aéroplane* there follows an extract from the conditions governing the military aviation contest at San Diego, Cal., in October, 1914. The conditions bear date July 1, 1914, and, as before, were fixed by the United States Army Signal Corps.

"The type desired, namely, a military recon-

noissance aeroplane, must possess the following characteristics: biplane, inclosed fuselage, two-seated, dual control, and have a minimum speed of not less than 40 miles per hour when carrying fuel and oil for four hours' flight at 70 miles per hour and a useful load of 450 pounds, and under these conditions of load to climb 4000 feet in 10 minutes. The head resistance is to be kept down by avoiding unnecessary parts exposed to the wind and by using recognized stream lining for those parts necessarily exposed. The power plant is to be located in front of the occupants and suited to the requirements of the aeroplane. The motor must be capable of throttling to 20 per cent of full speed and running without overheating over the land. The motor must be supplied with a positive means of stopping by a short-circuiting device, by release of compression, or by other suitable means. It is desirable that the radiators, if used, should conform to stream-line requirements and act as an effective shelter for the motor. The motor should be provided with positively driven pump for pumping gasoline from the reservoir to the service tank and will also be provided with attachments for hooking on a flexible tachometer, the shaft for this purpose to come off the motor at right angles to the propeller shaft preferably downward. The propeller or propellers should be of sufficient form and construction and suited for the particular machine and possessing a minimum efficiency of 70 per cent, that is to say, to have a slip of not over 30 per cent. Wear and friction in the control leads must be eliminated in every possible way and the leads shall be as direct as possible. Leads to pitching and steering shall be in duplicate. The landing gear to be as strong and simple as possible to be efficient in absorbing shocks in landing and running at full speed over rough and plowed ground. The maximum gliding angle shall under no condition exceed 1 on 6, that is to say, one foot of drop for each six feet of advance. All parts shall be efficiently protected from the action of the weather by the use of suitable paint or furnished with covers. The power plant shall be so arranged as to be readily removed and replaced bodily without disturbing the alignment or the fastenings of the planes or landing gear. The machine complete shall be capable of being assembled from transportation cases in not to exceed two hours by four mechanics and of being disassembled and packed in transportation cases in not more than one hour and a half by the same number of mechanics. No part shall be of such length that when packed in its case the case shall exceed 20 feet in length."

Bibliography. In addition to the works listed in the bibliography under AERONAUTICS there are available the following official reports and other works the range and number of which constantly are increasing: *Military Aviation*, April 26, 1912 (Washington, 1912); *United States Senate Report 1107*, Jan. 14, 1913 (ib., 1913); Committee on Military Affairs, *Aeronautics in the Army*, House Report, 5304, 1913 (ib., 1913); *Reports of the Chief Signal Officer*, U. S. A., especially 1914, and official reports generally (ib., 1914); R. P. Hearne, *Airships in Peace and War*, being the second edition of *Aerial Warfare* (New York, 1910); Grahame-White and Harper, *The Aeroplane in War* (Philadelphia, 1912); Bertrand, *Etat actuel de l'aéronautique militaire et navale* (Paris, 1913); Faroux and Bonnet (eds.), *Aéro-manuel*, 1914

(ib., annually); Rasch & Hormel (eds.), *Taschensbuch der Luftflotten*, 1914, 1915, the latter a war edition (Munich, annually); Hamel and Turner, *Flying* (London, 1914). All military journals and reviews contain articles on military aeronautics, e.g., the *Revue d'Artillerie* (Paris), *Army and Navy Journal* (New York), *United Service Magazine* (London), *Artilleristische Monatshefte* (Berlin). To give a list would be simply to name here the important military periodicals of the world. The general aeronautical periodical press (see article AERONAUTICS) may be profitably consulted. In the technical though nonmilitary press, such as the *Scientific American* (New York), may also be found from time to time articles of value. See AERONAUTICS; ARMY ORGANIZATION; MILITARY, OR MAN-RAISING, KITE; NAVAL AERONAUTICS; RECONNOISSANCE; SIGNAL CORPS; STRATEGY; TACTICS; WAR IN EUROPE.

MILITARY ARCHITECTURE. The various branches of architecture concerned with the design and construction of buildings for distinctly military purposes. Until the early Middle Ages, military architecture consisted almost entirely of the building of strong walls, towers, and gates around cities and permanent camps. For the engineering of works of defense, see FORTIFICATION.

Egypt. The earliest completely fortified city in good preservation is El Kab in Egypt, which formed a parallelogram of about 1500 by 2000 feet. The walls were of brick, over 30 feet thick and less than 30 feet high, with gates only on two sides. There were no towers, no moats, and the gates were merely openings. Such walls have been found at Thebes, Heliopolis, and in many other cities. Egyptian engineers, however, were sufficiently skillful in the Middle Empire (2000 B.C.) to take advantage of the natural defensive features of rocky situations and to abandon the defective rectangular ground plan; this is evident at Kummeh and Semneh at the Second Cataract, built to protect Egypt from Nubian invasions. Crude brick was the material, projecting buttresses strengthened the walls at intervals, and there were stations where archers could protect the approaches; the wide moat which encircled the fort was defended by a low stone wall; the interior of the fort was filled up solid to the level of a chemin de ronde. The Hittite wars made the Egyptians acquainted with the far more advanced systems of western Asia. Towers, bastions, elaborately fortified gates, and the use of stone for brick were some of the results.

Western Asia. The use of crude brick has made impossible any detailed knowledge of the methods of fortification used in Babylonian cities, though they are known to have been protected by walls of immense thickness and height. The plan of placing the Royal Palace on one side and using it as a citadel, of rectangular shape, was followed by the Assyrians, as shown in the city of Sargon, near Nineveh. But it was in the more mountainous countries of western Asia, especially in Syria and Armenia, that the earliest really scientific types of military engineering were thought out. The rectangular type was abandoned in favor of the circular or ovoidal, by which the weak angles were entirely avoided. In place of a single wall with an advance wall or scarp, there were usually three concentric lines of increasing heights, each with towers and battlements and chemins

de ronde. The Hittite cities were the most famous of such fortifications, from which both the Egyptians and Assyrians learned much. The mountainous races of western Asia thus created a type that was long to remain the highest known to military architecture and to be perpetuated by the successors of Alexander, by the Byzantine emperors, and by the Crusaders.

Ægean Peoples. The Pelasgians and other Ægean peoples built also in stone, often with Cyclopean and polygonal masonry. There were many types: first, the groups of defensive forts on the outskirts, or constituting a citadel; then later, the walls encircling the entire city. This wall sometimes rises 60 to 70 feet; the citadel as much more. The walls of Tiryns, with chambers within their thickness, and the Lion Gate at Mycenæ, defended by a narrow passage or *dromos*, are especially famous.

Greek. The great majority of fortifications found in Greece belong to the prehistoric period just described, e.g., those in Acarnania, at Orchemenus and Phigalia. The advances made in later historic times are shown, e.g., at Mantinea, with two round towers protecting its double gate, and especially at Messene, with gates within large towers having a circular inner court. The towers are battlemented and are sometimes rectangular. Wherever a suitable rugged eminence permitted, a citadel was established, inclosed by walls and difficult of access, as at Athens. See CITADEL.

Roman. The walls of Pompeii, of Aosta, and of Rome are a few among many examples showing the use of a simple encircling wall. The walls of Aurelian around Rome show three tiers of defenses, two lines of embrasures opening on galleries, and the *chemin de ronde* behind the battlements, besides a fourth and higher line at the summit of the numerous square towers. A unique combination of camp, palace, and fortress was Diocletian's palace at Spalato, also a superb work of late Roman architecture, with heavily projecting circular and rectangular towers.

Byzantine. The Eastern Empire continued the traditions of the ancient Orient. Antioch, Edessa, Constantinople, Amida, and other great cities trace their genealogy from Alexander's successors to Justinian. The essay of Procopius on the fortresses of Justinian shows how the Byzantine science of fortification was then being revolutionized under this Oriental influence, as in the great works at Dara. Between the towers permanent *échauguettes* and *machicoulis*, hurdles, or overhanging galleries, were built—originally of wood, but then of stone, in order better to let missiles fall on the besiegers. The system of several concentric walls triumphed permanently over the single rectangular Roman circuit. The citadel was not, as with the Romans, placed in the centre, but in touch with one of the outer walls, so that, if the city were taken, communication could still be maintained between the citadel and the outside world. Their system was adopted throughout the Empire and even in Europe, under Justinian. The walls of Constantinople, though in ruins, still exist—both the land walls and a part of the seaward defenses.

Mohammedan. In the great wars with the Byzantine Empire the Arabs quickly learned the science of military engineering, especially after the titanic struggle with the Macedonian

dynasty in the ninth and tenth centuries. Syria, Mesopotamia, Armenia, and Asia Minor are still covered with the ruins of forts, castles, and fortified cities of this period. The triple-walled citadel of Cairo was erected by architects from Syria. When the Crusaders came to the East, they came into contact with these two forms of Oriental engineering and borrowed its ideas for the West. The golden age of military works in the Orient extended from the ninth to the twelfth century. The combination of citadel and palace, which did not originate in Europe until the fourteenth century, was then a common thing with the emirs of the Mohammedan world; many such castles, of which the Granada Alhambra is an example, are still found in ruins—sumptuously beautiful within, magnificently strong without. The Seven Towers at Constantinople and the two castles of Hisar on the Bosphorus represent the highest development by the Turks of Byzantine models (fifteenth century).

Mediæval Europe. With the barbarian invasions of the fifth and sixth centuries there had been a veritable fury of haste to fortify the cities throughout the Roman world. This was particularly noticeable in Gaul, e.g., at Grenoble and Vienne, and in Spain, as at Cartagena. Mediæval cities often—as at Carcassonne—have their later fortifications based on late Roman or Gothic prototypes. But ordinarily the Roman fortification was a *castrum*, which did not inclose the city. City defense seems to have remained at a higher level than feudal castle architecture until the twelfth century, for while castles long remained mere earthworks in the north of Europe, cities had stone walls and even, as at Piacenza, two concentric circuits; and while the castle keeps were rectangular and in the centre of the circuit, the citadels were often curvilinear and astride the outer walls. For a well-preserved fortified city the best example is Carcassonne in southern France, built during the twelfth and thirteenth centuries. It has an inner and an outer circuit with towers of several shapes, bastions, and *barbicans*, with a magnificent citadel on the west edge. Avignon, Cologne, Cracow, Aigues-Mortes, Lucerne, Rothenburg, and Nuremberg have more or less complete mediæval fortifications, mostly of somewhat later date.

In the thirteenth and especially the fourteenth and fifteenth centuries in Europe æsthetic beauty was to an eminent degree united with military science in the design of fortress castles. This transformation is exemplified by such structures as Vajda-Hunyad Castle in Hungary, Marienburg in Prussia, and the ducal castle of Milan. The rebuilt castle of Pierrefonds in France carries this conception to its utmost limit. The city gates, as at Lübeck, Cologne, Tangermünde, Stendal, became works of municipal decoration as well as defense. A like combination of art and science was practiced during the Renaissance in Italy: accomplished artist architects like San Michele, San Gallo, and Michelangelo were employed to design fortifications and city gates: e.g., the *Porta Nuova*, *Porta del Palio*, etc., at Verona, the *Porto del Lido* at Venice, the fortifications of San Miniato, etc. After the seventeenth century the work of the architect was more and more severed from that of the engineer. Architecture as distinguished from military engineering at the present day is confined to the designing

of barracks, storehouses, stables, workshops, hospitals, and other buildings required for military purposes but not in themselves defensive. See BARRICAN; BASTION; BASTILLE; CASTLE; CITADEL; DONJON; EMBRASURE; FORTIFICATION; GATEWAY; PORTCULLIS; POSTERN; WALLS; and bibliographies under FORTIFICATION and CASTLE.

MILITARY BAGGAGE. See BAGGAGE, MILITARY.

MILITARY BRIDGES. See BRIDGES AND DOCKS, MILITARY.

MILITARY COMMISSIONS. Special military courts created during the occupation of conquered territory, for the trial of offenses which cannot by the rules of war be tried or punished by courts-martial, and yet which are not within the jurisdiction of any existing court. A military commission, unlike a court-martial, is exclusively a war court. It may be legally convened and assume jurisdiction only in time of war or when the civil authority is suspended on account of the existence of martial law or military government. The powers and procedure of this class of military tribunals have not been defined by statute law nor have they even been expressly authorized by any act of Congress, although they have repeatedly been recognized by the legislative, executive, and judicial departments of the government. According to usage the same rules which apply in the organization and procedures of courts-martial are held to be applicable to military commissions, and their proceedings are subject to review in the same manner and by the same authority as courts-martial. Certain offenses which in time of peace are regarded as civil offenses become in time of war military offenses and are triable by military commission, even though the civil courts may be open and in the unobstructed discharge of their duties. During the Civil War and Reconstruction periods capital offenses were frequently tried by military commissions and the parties punished, although they were in neither the military nor the naval service and in spite of the constitutional provision that all persons held for capital or otherwise infamous crimes, except when arising in the land or naval service, shall be tried by jury. Consult S. V. Benet, *Treatise on Military Law and the Practice of Courts-Martial* (6th ed., New York, 1868), and W. E. Birkhimer, *Military Government and Martial Law* (2d rev. ed., Kansas City, 1905). See COURTS, MILITARY; MLLIGAN, EX PARTE; MILITARY LAW.

MILITARY COURTS. See COURTS, MILITARY.

MILITARY EDUCATION. The education of the modern military officer may be divided into two parts, the preparatory and the technical. The increased demands made upon him in the exercise of his profession entail a most exacting and comprehensive preliminary training—so much so that in many countries candidates for army commissions are trained from earliest youth and molded mentally and physically for their future career. Below is a review of the systems of military education as practiced in Europe and the United States.

In Austria army training for cadets begins between the ages of 14 and 17, there being a number of schools (Realschulen) set apart for that work. Of these the greatest number are for the infantry, then the remainder for artillery, cavalry, and pioneers respectively. On graduation cadets are taken into the army as cadet

officer substitutes (*Cadet-officier-stellvertreter*) and granted commissions according to seniority, each selecting his own regiment or corps in the branch to which he is assigned—subject to the approval of the officers of such regiment or corps. In addition to these schools there are four military preparatory schools, a military orphanage, and the upper military school, whose pupils, sons of officers without means, enter the academy of Wiener-Neustadt, with its three years' course for cavalry and infantry officers, and the Technical Academy of Vienna, with a similar course for artillery and engineer officers. Pupils unfitted for the courses of these academies go to the cadet schools (Realschulen). Pupils capable of passing the entrance examination of the academies may enter direct. German is the language used in all military educational establishments, the curriculum also being based on the German system. For officers there are at Vienna the war school (staff college) and the superior artillery and engineer schools.

Belgium, previous to the great war, trained the officers of all arms at the Ecole Militaire, Ixelles, the course covering a period of two years for infantry and cavalry and four for artillery and engineers. Entrance is gained by competitive examination, there being an average of 80 vacancies in the school each year.

England possesses two military educational institutions: the Royal Military Academy at Woolwich, which is set apart for Royal Engineers and Royal Artillery cadets; and the Royal Military College at Sandhurst for cavalry and infantry cadets. No one is allowed to compete who has not been passed by the Army Council as socially qualified to hold a commission. The entrance examinations are conducted under the supervision of the Civil Service Commissioners, and there is also a rigid physical examination. The age of admission is from 17 to 19½ years for Sandhurst, and from 16½ to 19½ years for Woolwich, successful candidates paying half-yearly fees, the amount of which varies with the status, official or otherwise, of their families. At Woolwich the period of instruction covers two years and is divided into four classes, of which the fourth is the junior. The third and fourth classes are educated together, but on passing out of the third class into the second, the cadets are separated into two divisions, engineers and artillery, where they remain until graduation. Those passing out of the third class with the best percentage of marks go to the engineers, and the remainder to the artillery. Once the assignment has been made to any particular division a transfer is never allowed. The Royal Military College at Sandhurst is confined to cadets for cavalry and infantry, the entrance examination, fees, and academic terms being similar to the Royal Military Academy. A few cadets are received as royal cadets, or India cadets, who enter without payment and receive a small allowance. They are usually specially favored sons of poor or distinguished officers or have served as court pages. The course of instruction extends over a period of 18 months, divided into three terms, or classes of six months each, known as junior, intermediate, and senior. The peculiarity of the British method of instruction, compared with that of all other countries, is the brief period of instruction in the schools and the very exacting competitive standard and examination for admission, which, as well as the expense

involved at the very outset, limits the class from which cadets are drawn.

Schools of application are the Royal Engineers' at Chatham, the School of Gunnery at Shoeburyness, the Artillery College at Woolwich, the School of Musketry at Hythe, and the Staff College at Camberley. The Army Medical School at Netley trains candidates for appointment in the Royal Army Medical Corps. For schools for rank and file, see ARMY SCHOOLS.

France has two celebrated Cadet schools: (a) The Polytechnique at Paris, founded in 1794, supplies not only officers of artillery and of engineers, but also officials of the scientific branches of the government, such as roads and bridges, mines, naval construction, etc.; (b) the Ecole Spéciale Militaire, founded in 1808 at Saint-Cyr, and hence popularly called Saint-Cyr, whose graduates enter the cavalry and infantry. Entrance is by competitive examination, and candidates must, on the first of January of the year of examination, be between 17 and 21 years of age. The course lasts two years. Under a law passed in 1905, candidates who have passed must serve one year in the ranks under exactly the same conditions as a private soldier. At the end of this year they enter the schools. This law is due to the democratizing tendencies of the French Republic and, inasmuch as in principle one-half of the officers come from the ranks, rests on the supposed necessity of unity of origin for all officers. The artillery school at Fontainebleau has two divisions, one preparing noncommissioned officers of artillery to become officers of that arm, the other of postgraduate studies for lieutenants of artillery. At Versailles are found the same arrangements for the engineers. The school of the train is attached to the artillery school. At Saumur is the postgraduate school for officers of cavalry, as well as a school for noncommissioned officers of cavalry, candidates for commissions. The corresponding school for noncommissioned officers of infantry is situated at Saint-Maixent, but, unlike the other arms, there is no postgraduate school for the infantry.

The Ecole Supérieure de Guerre (Superior War School), or staff college, at Paris receives, after examination, officers of at least five years' service for a thorough course in strategy, tactics, military history and policy, and other subjects relating to the conduct of war. Other schools are those of military administration, of the medical service, etc.

Germany. Officers of the German Army come from the Kriegsschulen (war schools), of which there are 11 in the Empire. All candidates for commissions, whatever their origin, must, after having been appointed Porte-épée Fähnrich, be graduated from one of these schools. The Porte-épée Fähnrich, in turn, are composed of two classes, *avantagurs* and cadets, and must satisfy certain conditions before being appointed, such as passing the examinations of the Central Board of Officers at Berlin, have served at least five months as private, etc. *Avantagurs* are young men who announce themselves as candidates for commissions; most of the officers come from this class, the remainder from the cadets, who are pupils of the 10 cadet schools. To these schools boys are admitted at 11 years of age; they remain until they are 15, when they are transferred to the Cadetten Hauptchule (principal cadet school) at Gross Lichterfelde near Berlin.

The course at the Kriegsschulen lasts 35 weeks and is so adjusted that four classes are graduated in three years. Officers of foot artillery and of pioneers pass to the artillery and engineer schools of application (Berlin and Munich). The Technical War Academy completes the training of officers in mathematics, mechanics, physics, chemistry, and engineering, in the application of these sciences in general, and in their special application to the military service. This academy is open to lieutenants of all arms, and the course lasts three years. There are three riding schools (Hanover, Dresden, and Munich); as the purpose of these schools is the development of equitation and horse training, they are hardly to be regarded as educational in the usual sense of the word.

Finally we have the Kriegs Akademie, or General Staff School, at Berlin. The purpose of this school is, through its course of superior military instruction, to disseminate in the army a knowledge of the higher questions of strategy and tactics, and of military policy as an element of national policy. Secondly this school serves to train officers for the staff. There is an entrance examination open to all officers of at least three years' service in a commissioned grade. The professors are drawn as a rule from the officers of the great general staff. There are no examinations, but very careful notes are kept of the progress, capacity, and ability of each student officer. These are sent at the close of the three years' course to the chief of the general staff, who makes them the basis of selection of officers to serve a detail in the great general staff. Munich has a similar academy.

Italy. Military schools in Italy are divided into three classes: (1) the college militari, or preparatory schools; (2) the military academies at Turin for engineers and artillery, and at Modena for infantry and cavalry; (3) scuole militari complementari (schools of application). The Scuola di Guerra, the school of application for artillery and engineer officers, is at Turin, and the cavalry school is at Pinerola. The courses of instruction at the military academies of Turin and Modena are three years and two years respectively. There is a school for underofficers at Caserta, where approved non-commissioned officers are educated for commission. In each arm of the service fully one-third of the commissions are held by men from the ranks.

Japan. The military academies of Japan compare very favorably with the best in Europe, being in effect organized, as is the army, on the German model. There are establishments devoted to military education under the Minister of War, including the school of military music and the various schools of application. In 1902 several parties of Chinese army officers were sent by their government to undergo a course of instruction at the Japanese Military Academy.

Russia draws most of her officers of cavalry and infantry from cadet (*youngster*) schools, of which there are a number in the Empire. Officers not coming from these schools are furnished by the military schools and by the corps of pages. Staff instruction is given at the Nicolas (Staff), technical artillery training at the Michael (artillery), technical engineer training at the Nicolas (engineer) academies respectively, all at Petrograd. The military law and the military medical academies are also situated at Petrograd.

Spain educates her infantry cadets at Toledo, cavalry at Valladolid, engineers at Guadalajara, artillery at Segovia, and administrative at Avila. Suitable academies have been established at these respective places.

United States. Military education in the United States is practically a university system, bringing as it does all the different branches of military education into one system and under the direct control and supervision of a body of specially qualified officers, making every part of the system effective. The United States Military Academy at West Point, N. Y. (see **MILITARY ACADEMY, UNITED STATES**), is the foundation of the entire system and is generally conceded to be unequalled in the thoroughness and comprehensiveness of its training. The practical education of the cadet, in its broadest sense, begins with his assignment to his regiment or corps, there being in addition an officers' school at each military post for elementary instruction in theory and practice. The special service schools or schools of application are: (a) the Coast Artillery School at Fort Monroe, Va., which has a division for enlisted men; (b) the Engineer School, Washington Barracks, D. C.; (c) the Mounted Service School, Fort Riley, Kans.; (d) the Army Medical School, Washington, D. C.; (e) the army service schools at Fort Leavenworth, Kans., comprising (1) the Army School of the Line, (2) the Army Staff College, (3) the Army Signal School, (4) the Army Field Engineer School, (5) the Army Field Service and Correspondence School for Medical Officers; (f) the Army War College (q.v.) at Washington Barracks, D. C. To these may be added the School of Musketry and the School of Fire for Field Artillery, both at Fort Sill, Okla., and the Aviation School at San Diego, Cal. A general supervision of all the different schools enumerated above is exercised by the general staff. Officers' schools at military posts, the army service schools, and the Coast Artillery School are open to National Guard and volunteer officers, as well as to graduates of military schools and colleges which have had regular army officers as instructors. Military education is also furnished by certain State and private schools and by the "Students' Military Instruction Camp." (For other schools, see **ARMY SCHOOLS**.) Information in respect of military schools must usually be sought in official publications. For the United States, consult especially I. L. Reeves, *Military Education in the United States* (Burlington, 1914).

MILITARY FRONTIER. See **FRONTIER, MILITARY; MILITARY GEOGRAPHY.**

MILITARY GEOGRAPHY. Geography is that branch of science which deals with the phenomena of the earth's surface. Military geography considers these phenomena in their relation to or as they influence the practice of the military art in each of its four subdivisions of strategy, tactics, logistics, and military engineering. Although military geography is concerned principally with natural physical features

and resources (physical geography) as modified artificially by man (topography), the statesman and soldier must also study the influence of political, historical, and commercial geography in so far as such influence is felt in national military policies. The knowledge gained from these studies is essential to the formulation of effective strategic plans designed with a view to realizing a particular national policy. The study of the geography and topography of possible theatres of war in the vicinity of political frontiers or boundaries develops a knowledge of military frontiers, i.e., those lines of positions naturally or artificially made strong in a military sense. These lines are usually located near, but are seldom coincident with, political boundaries.

Influence of Geography on Military Operations. In making a general preliminary study of a country with a view to analyzing former campaigns or preparing a plan for future military operations it is advantageous first to consider the great rivers. This has been well expressed and explained by Brigadier General May (*An Introduction to Military Geography*, London, 1909) in the following words: "In studying the military geography of a country we cannot do better than follow up the path of its great watercourses. We are soon in touch with questions of vegetation, of crops, of the distribution of domestic animals, with villages, towns, great cities, fortresses. We reach them by *communications*, and the story of a nation's struggles and growth hinges upon these. For communications govern supply, and supply governs war."

The details of the physical features of the theatre of war must be thoroughly studied beforehand in order to arrive at the character of the troops best suited to that terrain. The means of transportation also is determined by the character of the roads and trails forming the line of communications. In an open plains country with good roads a preponderance of mounted troops and wheeled transportation might be advantageous; in a rough, mountainous country only dismounted troops and mountain artillery, transported on mule back, might be possible. Great howitzers sufficiently mobile on the roads of continental Europe might be useless on American roads. Thus, calibre and power of artillery may be fixed by geography and topography.

The nature and quantity of food, fuel (including petroleum), and forage afforded by the country to be traversed; how the additional amounts required for great modern armies are to be obtained from their own or neutral countries; and by what lines of communication, sea or land, such supplies are to be transported to the main, intermediate, and advance bases—all these are questions of the greatest moment to the responsible statesmen and generals, and they all must be answered, in part, in geographical terms. Thus, physical geography, by giving a knowledge of the resources of all countries, and commercial geography, by affording a familiarity with all the sea lines of communication, are of the utmost value to these national leaders who foresee the inevitable conflicts resulting from national expansion.

Physical geography also treats of weather, climate, and seasons, and these directly affect military operations, both strategic and tactical, as well as questions of supply of food, clothing,

shelter, and transportation. To safeguard the health and comfort of men and animals on tropical service special precautions must be taken. A knowledge of the tropics is essential if proper preparations are to be made. The American campaign of Santiago in 1898 is an illustration of the almost disastrous loss of efficiency due to an inadequate appreciation of the difficulties of tropical service.

The influence of mountains on the strategy and tactics of the attack and defense has many historical instances. Opinions differ as to the relative value of a mountain chain to the offense and to the defense. But the attacker, if he knows his terrain, has the great advantage of being able to select the particular pass to be forced and of concentrating a superiority of numbers at this point before the defender, with difficult lateral communications, can concentrate his troops. The Alps were crossed by Hannibal, Francis I, and Napoleon. The Pyrenees have been crossed frequently by large armies. Alexander in his great march to India led his armies across mountain ranges which would try the skill and endurance of modern soldiers. Jackson in his valley campaign skillfully utilized the mountains as a screen and obstacle to a hostile attack on his flank in his advance paralleling the general trend of the Massanuttons.

Valleys, being the line of least resistance, determine the line of advance, communication, and supply. He who holds the valleys holds the country. Railroads follow the valleys, just as ancient military roads and trails followed the watercourses. It is for this reason that the modern general finds it useful to study the geography of ancient campaigns, the historical routes of barbarian invasion. In going from Constantinople to Vienna the modern traveler to-day passes over the Roman route by way of Adrianople, Philippopolis, Sofia, Belgrade, and Budapest.

Great valleys usually carry great rivers. Rivers may form obstacles, as in the case of mountain ranges, or they may be the principal lines of communication and supply when navigable. They often become the military or strategic frontiers, the defended passages of which form the crucial points during a campaign. Though offering serious difficulties as obstacles, they may be successfully crossed, as are mountain ranges, when the will and skill exist. The Danube, one of the greatest military barriers, has been crossed more than 20 times in the face of defending forces.

A river may guard the flank of an army advancing along its course or may determine the direction of march on account of water supply. Rivers must be studied with reference to strategical points and as a means of supply. The bridges, ferries, fords, roads to each; current, nature and height of banks, floods and ice conditions, must all be considered before military operations are undertaken. Although rivers form natural boundaries and effective military frontiers, it is noticeable in Europe that the expansion and contraction of states in the past has in most cases resulted in the elimination of rivers as political boundaries. Junctions of rivers may form important strategical points or keys, as they control the intersecting valleys and require a besieging army to advance with forces separated by the intersecting rivers.

In planning military operations it is always necessary to study the geography of the theatre

of operations with a view to selecting definite objectives, called strategical points, against which the operations are to be conducted. Such objectives may be political, commercial, or purely military, or all three. The objective, whenever practicable, should be so situated that an advance against it will surely threaten the principal line of communication and supply of the defending army. Examples of such points are important river crossings, mountain passes, rail way centres, capitals, water supply, a river port controlling access to the sea and to the interior, etc.

Sea power determines the ultimate eminence of a nation politically, and the development of such power is largely due to geographical location and conditions in relation to the sea. Great Britain's frontier is the sea, and her national existence in peace and war depends on sea trade and sea control. The materials for shipbuilding, coal, and iron are near her great seaports, which control the trade routes through the English Channel to the North and Baltic seas. Similarly, a geographical study of Japan's location and relation to the shores of the Pacific will give an insight into her aspirations and probable future development as the great sea power of the Pacific. For a complete understanding of the political and military history of any country—Germany, Russia, France, Spain, Italy, Holland, the United States—or their present international policies, we must study their geographical location with respect to the sea and the sea routes to other lands.

A knowledge of natural features as modified by man with harbor improvements, wharves, communication to the interior by river, canal, or rail are of utmost importance in planning combined operations of the army and navy. The great interoceanic canals, Panama and Suez, and their approaches introduced new policies and modified strategic plans. The attack and defense of a great seaport like New York involves a knowledge not only of harbor channels, but also (which is far more important) a detailed study of all adjacent landing beaches, tide, surf, prevailing winds, character of beach, lines of advance to the rear of the city and its coast defenses, and the natural positions for interior land fortifications to resist an assault from the rear.

The importance of lines of communication cannot be overestimated. In the words of General May, "Success or failure in war ultimately hinges on communications. That side which can stay the longest—that is to say, which continues to be fed and supplied and reinforced with regularity—will at length emerge victorious. Communications spell strategy, and it is generalship or strategy that wins wars, though it is possible for courage and skill at arms to win battles, or even campaigns."

Above we have touched upon the vital importance of the control of the high seas. On land one of the most striking developments of modern war has been the increased efficiency of railways. During the Russo-Japanese War (1904-05) it was freely predicted that Russia would fail because of the insufficiency and inefficiency of her means of communication by a single line of rail 5000 miles from Moscow. As a matter of fact Russia was able to assemble and maintain at a distance of 5000 miles from her base a force of over 1,000,000 men, a force which was but little less than that of Japan.

who was only six days by sea from her base. Strategic railways are being rapidly constructed not only in continental Europe, but in both Asia and Africa. It was to such railways constructed by Germany in time of peace that she owed her wonderful mobilization on both the western and eastern fronts in the Great European War of 1914. Her six main lines of railway to the French frontier, and those built to the frontiers of Belgium and Luxemburg, double-tracked and equipped with the most modern landing platforms and sidings, joined together by railways paralleling the front along the Rhine, enabled Germany to transport, with great rapidity, vast armies to any part of the French and Belgian frontier and to reinforce any threatened point by troops from any other point. On the Russian side Germany had 17 lines (23 tracks) leading to the frontier, by means of which she was able to dispatch 500 troop trains per day. Against these 17 lines Russia had only five. From Austria eight lines (10 tracks), with a capacity of 260 trains per day, run into the intrenched camps of Galicia, from which an advance into Russia may be made. Against these the Russians have only four lines of railway. Since 1905 the Carpathian Mountains have been pierced by five lines of railway and preparations made to lay three more. To these strategic railways was due the ease with which Germany carried the war into the enemy's territory and placed both France and Russia on the defensive at the very outbreak of the war.

Napoleon once said that "the frontiers of states are either large rivers or chains of mountains or deserts. Of all these obstacles to the march of an army the most difficult to overcome is the desert; mountains come next, and broad rivers occupy the third place." Since his day, however, modern railroad engineering has eliminated the terrors of deserts in Asia, Africa, and America, and thus compelled new policies and new strategic plans of offense and defense.

An article on military geography, no matter how brief, would be incomplete without some reference to buffer states, protectorates, and spheres of influence. Such terms designate the territory of weak states declared inviolate by the mutual agreement of stronger neighbors. Sometimes the purpose is to provide against aggression, sometimes to conceal preparations for aggression. In any case the weaker neutralized state is at the mercy of one or all the stronger. Switzerland, surrounded by France, Germany, Austria, and Italy, is an example of the geographical location of a neutral state influencing the strategy of her neighbors. Belgium, the cockpit of Europe, is an illustration of a buffer state used as the battleground for stronger neighbors. Luxemburg has a similar history. Afghanistan is a true buffer state between the Indian Empire of England and Russia.

The fundamental cause of war is national expansion, which means a forcible rearrangement of international boundaries. A study of the geography of frontiers is therefore most valuable to statesmen responsible for policy as well as to soldiers charged with the execution of policy. For these reasons we find that military geography is largely concerned with the subject of military frontiers—those selected and strengthened lines of defense established in the vicinity of international boundaries as a bulwark against aggressive neighbors. Under modern conditions

of war permanent fortifications constitute a minor part of frontier defense, the main reliance being placed on mobile field armies, for the movement of which in war there have been prepared in peace ample lines of communication leading to the national boundary, and lateral communications, connecting these, parallel to the general front. There is given below as examples a brief geographical outline of a few military frontiers as they existed at the outbreak of the European War in 1914. By reference to a suitable map there will be noted the location of the military frontier, and its rail and other communications, with reference to the international boundary protected.

France. Northern frontier, from Dunkirk to Longwy, 220 miles. Fortified towns: Calais, Gravelines, Dunkirk, Bergues, Lille, Douai, Maubeuge, Mézières, Montmédy, Longwy. Between these are other fortified places, and behind this front a second line: Péronne, Arras, Laon, La Fère. Eastern frontier, from Longwy to Delle, 240 miles. The line of defense extends from Mézières through Verdun, Toul, Epinal to Belfort. Verdun is a fortress of the first class and is on the direct road from Metz to Paris. Between the places given are many minor fortifications. Behind this front is a second line: Rheims, Langres. Still further to the rear is Paris, with its circle of fortifications.

Germany. Here we find a different and more modern principle of defense, noticeably in the absence of fortifications. The Vosges Mountains on the boundary constitute a natural military frontier or obstacle. The only great fortifications are the entrenched camps of Metz and Strassburg. Behind these flows the Rhine, a natural obstacle with guarded passages and a railway on each bank for lateral communication along the front. There is a second line with a few strongholds: Mainz, Coblenz, Cologne, New Breisach, Diedenhofen, Bitach, and Rastatt. Berlin, unlike Paris, is not defended by great fortifications. Germany's frontier dispositions foretold what the European War of 1914 proved, viz., that the defense of her territory would be accomplished by promptly assuming the initiative and carrying the fight into Belgium and France. On the northeast front there are important fortifications: Danzig, Thorn, Gaudenz, Dirschau. To the northeast of Danzig the strong fortress of Königsberg, with its adjacent strong places at Pillau and Memel, and Boyen near Lötzen. West of Thorn is Bromberg and to the southwest Posen, with strong places. Since the Oder offers an easy advance to Berlin, the fortifications at Glogau have been constructed. Still farther to the south is Neisse.

Bibliography. For other European military frontiers and the geographical reasons for their selection and fortification, consult May, *An Introduction to Military Geography* (London, 1909). On account of the past isolation of the United States with respect to great military powers there is but little published technical literature on the subject of its four great frontiers—the Atlantic, the Pacific, the Canadian, and the Mexican. Expert technical studies have been made by officers of the general staff, but the records of these studies are to be found only among the confidential records of the War College at Washington. However, an interesting geographical military study of the Pacific coast, by a civilian, is to be found in Homer Lea's *Valor of Ignorance* (New York, 1909). A read-

ing of this book will suggest the absorbing interest and great value of geographical studies in relation to general national and military policies.

Consult also: T. M. Maguire, *Military Geography* (New York, 1900); James, *Modern Strategy* (London, 1904); Lyde and Ferryman, *Military Geography of the Balkan Peninsula* (New York, 1905); A. C. Macdonnell, *Outlines of Military Geography* (2 vols., London, 1911); United States Army Service School Press, *Moltke's Correspondence* (Fort Leavenworth, Kans., 1911).

MILITARY GOVERNMENT. The administration of territory taken from the enemy which is authorized under martial law (q.v.). It is under this power, arising from the necessity of the case, that provisional governments are instituted in conquered territory. All proceedings of government under martial law are, within the scope of their authority, as legal and constitutional as any other military proceedings. Military government is more properly applied only to governments established in territory outside the boundaries of the state to which the troops establishing it belong. Military rule established in disturbed areas of a state to which the force establishing it belongs is more properly to be termed martial law (q.v.).

MILITARY HONORS. Compliments paid to certain officers, officials, or other distinguished persons. See SALUTES; HONORS, MILITARY.

MILITARY HOSPITALS. See HOSPITAL.

MILITARY HYGIENE. See HYGIENE, *Military Hygiene*.

MILITARY INSIGNIA. Devices used to distinguish the various corps, branches, ranks, and grades of the military and naval services. In all the armies of the world it has been found necessary to employ badges and devices to mark the necessary distinctions incident to such organizations. The term "insignia" is here employed to include such badges, devices, etc., in contradistinction to equipment, clothing, etc. The custom in Europe is a natural result of the evolution of the various countries both politically and militantly, and in the case of England particularly the badges, mottoes, and devices used by the various regiments are emblematic of conspicuous incidents in their history and not infrequently have been taken in battle from some regiment of the enemy.

Commencing with the insignia distinguishing the various grades of rank, German usage may be described at length, seeing that its system in a large measure obtains in every other army in Europe. Throughout the Imperial army the epaulets of all commissioned ranks are crescent-shaped. The various grades are distinguished as follows: 1. General field marshal, two batons (staves of command crosswise over each other). 2. General in chief, three stars. 3. General of the infantry, cavalry, or artillery, colonel, captain, two stars. 4. Lieutenant general, lieutenant colonel, first lieutenant, one star; major generals, majors, and second lieutenants do not wear a star. Second and first lieutenants and captain wear epaulets having a gold rim but no trimming; colonels, lieutenant colonels, and majors wear epaulets with gold rims and silver trimming. The general field marshal, general in chief, lieutenant general, and major general are distinguished by the silver rims and silver trimming of the epaulets. The noncommissioned ranks are distinguished by the gold or

silver lace on the collars, cuffs, and facings of the tunics. On the shoulder straps is the number of the soldier and the monogram of his regiment. The various arms of the service are also distinguished by the color of the tunic lace; e.g. infantry regiments have red lace. On the right side of every German soldier's helmet is placed the black, white, and red cockade of the German Empire, while the cockade on the left side indicates the particular state of the German Confederation to which the regiment belongs, as follows: Prussia, black-white; Bavaria, white-sky blue; Hamburg-Bremen-Lubeck, white with red cross; Saxony, white-green, Württemberg, black-red; Baden, yellow-red; Hesse, white-red; Mecklenburg, sky blue-yellow-red; Oldenburg, white-dark blue with red cross; Saxe-Weimar, yellow-green; Brunswick, sky blue-yellow; Anhalt, green; Saxon duchies, green-white; Lippe, yellow-red; Schaumburg-Lippe, white-red; Waldeck, yellow-red; Schwarzburg-Sondershausen, white-dark blue; Schwarzburg-Rudolstadt, dark blue-white; Reussa, yellow-red. Other distinguishing marks between the various services of the German army are found in the color of their uniform, for which see UNIFORMS, MILITARY.

In the British army insignia play an important part. They are used as much to encourage esprit de corps as a mark of distinction between regiments. There is a large degree of variety in the badges in use among the various regiments of the army, most of them reminiscent of stirring periods in regimental history. In 1836 the King commanded that an account should be published concerning the insignia, badge devices, etc., of the regiments of the army, together with the particulars recounting the reasons for their existence. The result was a very excellent history of the British army. The introduction of the territorial system in 1881 destroyed in a measure the individuality of the regiment and made it a part of the territorial district to which it was assigned. In the effort to bind still further the regiment and its district together the attempt was made by the military administration to abolish many of the insignia formerly characteristic of the different regiments. The attempt, however, created so much opposition and ill will among all ranks of the army that a compromise was effected, and to-day nearly all the old devices are employed, the expense usually being borne by the officers of the regiment. The authorized and unauthorized badges include the royal arms (in the case of the guards and all other regiments distinguished by the prefix "royal"), the whole or part of numerous orders, and other royal honors. Still others are purely regimental, i.e., badges distinguishing regiments of the same arm, as castles, arms of counties and cities, the Prussian eagle, the French eagle, the death's head, the elephant, the antelope, tiger, dragon of Wales, dragon of China, the sphinx of Egypt (this is worn by the 30 regiments who served in the first English expedition against the French in Egypt), the Paschal Lamb, the white horse of Hanover, the white horse of Kent, the lion of England, a gun, a grenade, the bugle (all light infantry and rifle regiments are distinguished by this badge), the bear and ragged staff, the figure of Britannia, St. George and the dragon, the harp and crown, the shamrock (as in the case of the newly formed Irish guards), the Scottish thistle, the Cross of St. Andrew, and many others. The royal arms are borne by the Royal

Engineers and the Royal Artillery, the difference between them being in the mottoes, *Quo Fas et Gloria ducunt* and *Ubique*. With the latter motto is coupled an artillery gun.

As with Germany, the various branches, arms, departments, etc., of the service are distinguished by their distinctive uniforms and not by any particular badge. In the mounted branches rough riders (or young horsemen) are distinguished by a spur worn above the elbow on the sleeve of the tunic; farriers and shoeing smiths wear a horseshoe. Expert swordsmen and gymnasium instructors of all branches wear the crossed swords. Marksmen (sharpshooters) of all arms wear the crossed guns placed immediately above the cuff of the tunic. Pioneers wear the crossed axes on the upper sleeve. Commissioned and noncommissioned ranks of the infantry wear the sash, which in the case of officers is of silk and is worn over the left shoulder, and with noncommissioned officers is of worsted and worn over the right shoulder. Scottish Highland regiments are further distinguished by the differences in pattern of their clan tartans. See UNIFORMS, MILITARY.

In the United States at the time of the Revolution the distinguishing characteristics of army ranks were largely copied after French, Prussian, and English usages. General and staff officers were distinguished by the color of their sash or ribbon, which was worn over the waistcoat and under the coat. Cockades were worn by all other commissioned officers, and the noncommissioned officers were distinguished by the color of their epaulet. On June 18, 1780, a general order was promulgated authorizing the following insignia of rank and grade: major generals to wear two stars on each epaulet; brigadier generals, one star; field officers wore two epaulets; captains, one epaulet on the right shoulder only; lieutenants, one epaulet on the left shoulder. Other distinguishing marks were details of uniform. In 1782 the system of wearing stripes as badges of rank and service by the rank and file was instituted. Changes were frequent up to the Civil War, but the insignia since that time have remained substantially the same, the more important changes, particularly those of 1902, having had to do with uniform and equipment rather than with insignia. Officers' insignia (1914) are as follows:

(a) The letters U. S., of Gothic design, made of gold or gilt metal or dull-finish bronze, worn on the collar of the dress, service, or white coat, are placed at a distance of 1 inch from each end of the collar. When worn upon the dress or white uniform, the letters are of gold or gilt metal (of silver for Engineers). When worn upon the service uniform, they are of dull bronze metal. To designate officers of volunteers these letters are followed by the letter V.

(b) The insignia of corps, department, or arm of service are as follows: General Staff Corps, the United States coat of arms, of gold and enamel, superimposed on a silver star; Adjutant General's Department, a shield 1 inch high, $\frac{3}{4}$ inch wide; Inspector General's Department, gold or gilt sword and fasces crossed and wreathed; Judge-Advocate-General's Department, sword and pen in gold or gilt metal, crossed and wreathed; Quartermaster's Department, sword and key crossed on a wheel, surmounted by a spread eagle of gold or gilt metal, platinum and enamel; Medical Corps, a caduceus of gold or gilt metal; Medical Reserve Corps, same with

letters R. C.; Dental Surgeon, same with letters D. C.; Acting Dental Surgeon, D. S., the caduceus of silver; Corps of Engineers, a silver turreted castle; Ordnance Department, shell and flame, of gold or gilt metal; Signal Corps, two crossed signal flags and a burning torch, in gold and silver; chief of the Bureau of Insular Affairs, seven arrows with wings on sides, 1 inch high, in gold or gilt metal; professors and associate professors of the United States Military Academy, shield and helmet surrounded by a scroll, in gold or gilt metal; aids-de-camp, a device $1\frac{1}{2}$ inches high, consisting of a shield of the United States, of properly colored enamel $\frac{3}{4}$ inch high and $\frac{3}{4}$ inch wide at top, surmounted by a gold or gilt eagle, with wings displayed, on blue field of the shield a star or stars, according to rank of the general on whose staff the officer is serving. This device is worn on the collar in lieu of corps or line device.

The devices appropriate to the various arms of the service are as follows: Cavalry, two crossed sabres, 1 inch high, with number of regiment above intersection; of gold or gilt metal. Field Artillery, two crossed field guns, design to be 1 inch high, of gold or gilt metal, the number of the regiment $\frac{3}{8}$ inch high in the upper angle. Coast Artillery, two crossed cannon, with oval at centre carrying a projectile, point up. Infantry, two crossed rifles, design to be 1 inch high, with number of regiment above intersection; of gold or gilt metal. Regimental adjutants, quartermasters, commissaries, and artillery district adjutants wear in the lower angles of their insignia the devices (of gold or gilt metal) of the respective departments to which their duties correspond; the battalion adjutant and quartermaster of engineer battalions wear the same devices above the centre turret. Chaplains, the same as for regimental staff officers, except that the pendant design is a Latin cross of the same material and size. The insignia of corps, department, or arm of service is placed upon the collar of the dress, service, and white coat $\frac{5}{8}$ inch from the letters U. S. and is of gold or gilt metal with the dress or white uniform and of dull bronze metal with the service uniform. Veterinarian, device of arm of service, with foot of a horse in lower angle, number of regiment in upper angle.

(c) The insignia of rank are placed on the shoulder loops of the service coat and the white coat near the shoulder seam, also on the shoulder knots, as follows: General, coat of arms of United States between two stars; lieutenant general, one large star between two small stars; major general, two silver stars; brigadier general, one silver star; colonel, one silver spread eagle; lieutenant colonel, one silver leaf; major, one gold leaf; captain, two silver bars; first lieutenant, one silver bar.

Sleeve insignia of rank: major general, two silver stars; brigadier general, one silver star; colonel, a single knot composed of five strands of gold-wire lace, not exceeding $\frac{1}{8}$ inch in width, applied to the sleeve of the full-dress coat below the elbow, the base resting on the gold band of the sleeve; lieutenant colonel, four strands, single knot; major, three strands, single knot; captain, two strands, single knot; first lieutenant, one strand, single knot; second lieutenant, without gold lace; chaplain, without gold lace. The outside dimensions of the gold-lace insignia are the same for all officers, the dimensions being made by taking strands from the interior. Metal

insignia of corps, department, arm of service, or aid-de-camp are placed in the centre of the open space under the lace insignia, except for general staff officers, who wear the corps insignia on the shoulder knot.

Sleeve insignia for overcoats, made of flat black mohair soutache braid $\frac{1}{8}$ inch in width, follow the form of the gold-lace insignia for dress coats, but are applied with the base resting at lower end of the sleeve. Insignia of corps, etc., are not worn on the overcoat.

Epaulets: for general officers, of gold with solid crescent, the devices being the coat of arms of the United States embroidered in gold, and one star for brigadier general, two for major general. For general staff officers the insignia of the corps replace the coat of arms of the United States.

Shoulder knots: of gold-wire cord $\frac{1}{4}$ inch in diameter, formed of three cords in four plaits and rounded top, finished with small gilt regulation button; about $5\frac{1}{2}$ inches long and $2\frac{1}{2}$ inches wide, extending from the seam of the sleeve to the seam of the collar; slightly stiffened with a flexible backing which is covered with cloth of the color of the coat and made detachable; insignia of rank to be worn on knot.

Shoulder straps are as follows: general—dark-blue cloth, $1\frac{1}{2}$ inches wide and 4 inches long, bordered with an embroidery of gold $\frac{3}{8}$ inch wide; the field of strap to be of cloth the color of the facings of corps, department, or arm of service; the insignia of rank to be placed in field of strap as follows: general—two silver-embroidered stars of five rays each and gold-embroidered arms of the United States; lieutenant general—three silver stars. Major general—the same as for a lieutenant general, except that there are two stars instead of three; the centre of each star to be 1 inch from the outer edge of the gold embroidery on the ends of the straps; both stars of the same size. Brigadier general—the same as for a major general, except that there is one star instead of two at the centre of the strap. Colonel—the same as for a brigadier general, omitting the star, with a silver-embroidered spread eagle on the centre of the strap. Lieutenant colonel—the same as for a colonel, according to corps, department, or arm of service, omitting the eagle, with a silver-embroidered leaf at each end, each leaf extending $\frac{1}{8}$ inch from the end of the strap. Major—the same as for a lieutenant colonel, with a gold-embroidered leaf at each end, instead of silver leaf; each leaf extending $\frac{1}{8}$ inch from the end of the strap. Captain—the same as for a major, omitting the leaves; at each end two silver-embroidered bars of the same width as the border, placed parallel to the ends of the strap; the distance between them and the border equal to the width of the border. First lieutenant—the same as for a captain; at each end one silver-embroidered bar of the same width as the border, placed parallel to the ends of the strap, at a distance from the border equal to the width of the border. Second lieutenant—the same as for a first lieutenant, omitting the bars. Additional second lieutenant—the same as for a second lieutenant. Chaplain—of dark-blue cloth of the usual size and pattern, with a plain Latin cross of silver in the centre.

Corps badges were first employed during the Civil War and proved to be an extremely valuable means of identification. The devices employed include a triangle (Fourth Army Corps);

the star and crescent (Seventh); a six-pointed star (Eighth); an acorn (Fourteenth); an arrow (Seventeenth); a maltese cross (Nineteenth); a shield (Twenty-third). The device for Wilson's cavalry corps consisted of crossed swords surmounted by a carbine. The Signal Corps was distinguished by the crossed flags and torch. Division headquarters were marked by a square flag upon which was a badge designating the character of the headquarters. The old Twentieth Corps did not at first wear a badge, but when the new Twentieth was formed by the consolidation of the Eleventh and Twelfth Army Corps, it adopted the badge of the Twelfth, a five-pointed star. During the Spanish-American War the various corps were distinguished by the following corps badges: Artillery Corps, crossed conical projectiles, with round shot above the centre; Cavalry Corps, a winged horse's foot; First Corps, the letter I inclosed in a circle; Second Corps, a four-leaf clover; Third Corps, a three-toothed clutch; Fourth Corps, a callrop; Fifth Corps, a five-battioned fort; Sixth Corps, a six-spoke hub; Seventh Corps, a seven-pointed star; Eighth Corps, two overlapping circles, very much resembling the figure eight; Ninth Corps, a nine-toothed buzz saw; Tenth Corps, two triangles point to point; Eleventh Corps, same design as for the Tenth Corps, with the addition of a horizontal bar through the centre; Twelfth Corps, a square with a clover leaf at each corner; Thirteenth Corps, a palm leaf; Fourteenth Corps, a square with half circles on each side; Fifteenth Corps, a bugle; Sixteenth Corps, a spearhead; Seventeenth Corps, a battle-ax; Eighteenth Corps, an arch. The color of the symbol determined the division of the corps, as: red, First Division; white, Second Division; blue, Third Division. Such badges were worn on the hat or cap. Commissioned officers wore them on the left breast and not on the hat. See UNIFORMS, MILITARY AND NAVAL; AIGUILLETES; CHVRONS; ETC.

MILITARY JUSTICE, BUREAU OF. See MILITARY LAW.

MILITARY, or MAN-RAISING, KITE.

The man-raising kite as employed for military observation is in principle a "captive" or "anchored" aeroplane (see AERONAUTICS) in equilibrium under the action of three forces, the weight of the apparatus, the pressure of the wind, and the tension of the retaining cable. It is a military possibility because it is easily transported, may be used in a high wind, is quickly sent up, is safe, cheap, and easily repaired. Although of exceedingly limited application, it may yet, under special conditions, be of great value.

The possibility of using a kite for observation purposes is comparatively recent. Various models have appeared from time to time: Maillet's octagonal kite in 1886; Baden-Powell's hexagonal in 1894; Lamson's superposed planes in 1896; diedral kites, etc. But its serious practicability is due chiefly to the invention by Hargrave of the cellular or box kite. This consists essentially of two canvas parallelepipeds, presenting to the wind a double surface, one sustaining, the other directing; in reality it is a canvas beam, open at the ends and cut away in the middle. In the construction of the kite the important condition is to have a maximum sustaining surface and a minimum weight, without sacrificing the strength, the resistance of the system. Hence we have the so-called *density of*

the kite, the ratio of its weight to its bearing surface. Having the box kite then, the true solution of the problem was obtained when the idea of trains of kites suggested itself. By the application of this idea not only was the supporting power of the system increased, but its safety also; should one of the trains give way, the others would still hold. Observation from a kite is very convenient and safe; should the wind show signs of falling, the kite is hauled down. A squall even is not to be feared. It is noteworthy that the cable is but slightly influenced by changes of position of the kite in a gusty wind, and remains always stretched in the same direction, that of the prevailing wind. Hence the steadiness of the car, a valuable quality, especially if photographs are to be taken. Moreover, the observer is reasonably safe even under fire, for his stay in the air need be but brief; in other words, he may make his observations and come down before the enemy can get the range.

It is obvious that the possibilities of the man-raising kite are limited; it may, of course, accompany an army in the field, but cannot hope to compete with the dirigible and the aeroplane. Its chief application will be made in observing siege and fortress artillery fire; but even in these cases it will prove inferior to the captive or kite balloon. For one thing, in a given wind a kite will rise to a certain height, which it is useless to endeavor to exceed; any further attempt merely causes the kite to displace itself in the direction of the wind. According to one authority, Captain Saconney, of the French army, the useful limit of cable payed out is reached when the height of the car is equal to half the length of the cable unwound.

Two countries have made a specialty of the kite: Russia, in its navy chiefly, England in both army and navy. It is said that in England ascensions of 400 meters and even of 800 meters have been made. The results achieved excited attention in France; the outcome of the investigations and experiments was the Saconney apparatus, of which we shall here give a brief description. In this apparatus two cables are used; to one is attached a train of kites, called the principal train, the purpose of which is merely to raise its cable in the air. On this aerial rail, thus supported, runs a trolley, from which hangs the observation car, carried up by a second train of kites; the car is controlled by the second cable. The two cables are operated by a double winch driven by the motor of the automobile truck that transports the equipment when dismounted. This winch can take up cable at the rate of 180 meters per minute; should the principal train give way, this speed sets up a relative wind, sufficiently great to prevent accidents. The supporting cable is 5 millimeters in diameter, 1500 meters long, and has a resistance of 2000 kilograms; the car cable above the car is 5 millimeters in diameter, with a resistance of 2000 kilograms, and 3.5 millimeters below the car, with a resistance of 1000 kilograms; it is 1300 meters long.

The number of kites to be used obviously depends on the velocity of the wind that may be blowing at the moment. It is assumed that the traction of the cable is constant; this traction corresponds to a lifting effort of 300 kilograms sufficient to support the car, the observer, and the cable. This is always unwound to the same length, and its weight therefore does not change.

The "independent variable" of the problem is consequently the velocity of the wind to be determined by observation; the "dependent variable" is the number of kites. This number is determined as follows: 10 kites of 100 meters' bearing surface will in a wind of 10 miles produce the normal lifting effort of 300 kilograms. This rule is known as the "rule of 10." Modifications of the normal case are assumed to vary with the square of the ratio of wind velocities. Hence a wind of 5 meters per second will support only 75 kilograms, and to raise 300 kilograms, 40 kites will be needed, an impracticable result. A wind of 20 meters per second, on the contrary, would support 1200 kilograms; hence three kites would suffice. The importance of the number of kites appears when we consider that, if the number remained always the same, the stress of the system would be increased ninefold for an increase of the wind velocity from 8 meters per second to 24 meters per second.

The kite used is the Hargrave model, fitted with wings; the car is a wicker basket one meter deep. (See KITE for illustration and description.) In operation two methods of launching the system are followed: the first is known as that of "successive postillions," in which the pilot kite is sent up to say 100 meters, and the others are then successively attached and allowed to run up until they come against the stops, about 6 meters apart; these stops increase in size with the distance, as do the split rings by which each kite is slipped on to the cable. The cable is then paid out. If the wind is strong, the pilot is sent up to its full height, then in succession the remaining kites. In the second method the whole apparatus (with the pilot) is set up on the surface of the ground, ready for launching; at the word of command the pilot is released and takes up the system. The first method requires only a limited space, 30 meters long, the second a space 10 times as long. The complete operation may be carried out in 20 minutes by a crew of some training. Transportation is furnished by an automobile pulling a baggage wagon and carrying besides the crew of 16 men. Apparatus and automobile cost about \$3000, as compared with \$12,000 to \$15,000 for an aeroplane and \$500,000 for a dirigible. Communication is had with the ground either by visual signals or by telephone. For further details, consult *Revue d'Artillerie* (Paris, August, 1912). See KITE; MILITARY AERONAUTICS.

MILITARY LAW. That part of the law of the land which prescribes and enforces the public obligations of persons in the military service. The civil law not being adequate for the government of the military community, peculiar laws and institutions have been framed for its regulation, which invest military authority with the right to punish offenders who are under military rule for offenses contrary to military discipline, or breaches of military duty, the essential object being to maintain order and discipline in the army. Every country that maintains a standing army generally enacts articles for its government and confers special and limited powers upon the military authorities to enable them to enforce their provisions.

The Constitution of the United States confided to Congress the power to keep up a standing army and to make rules and regulations for its government. Under this grant Congress has

enacted Articles of War and other similar enactments which together constitute the statutory military law of the United States. These statutes deal not only with military offenses and punishments, but also with the constitution, composition, jurisdiction, and procedure of military courts. The power of the President to issue regulations and orders to the army is a right incidental to his constitutional power as commander in chief and is a means for carrying into execution his sovereign power. Such orders of the President, as commander in chief, and of superior officers, when not in conflict with existing law and regulations, are also a part of the code military. To declare what the law for the army shall be is the province of Congress; but to interpret this law is a judicial function. While American military law is mostly statutory, we must go to the decisions of the courts and to the opinions of the attorneys-general for interpretation and explanation of the enacted word.

Customs of the Service in peace and in war are a source of military law. These usages have become to the army a kind of common law, supplementing the statute law and regulations. The oath administered to the members of a court-martial requires them in doubtful cases to administer justice according to "the customs of war in like cases." This oath is almost identical with the one taken by members of courts-martial in the British service, and the term "custom of war" as used in the Articles of War of the United States must not be understood as referring only to the usages of the army of the United States.

Persons Subject to the Military Law are (1) officers and soldiers on the active list, whether militia or others, mustered and in pay of the United States, (2) retired officers and soldiers, (3) persons who fraudulently enlist and receive pay and allowances thereunder, (4) discharged officers and soldiers who have defrauded the United States, (5) discharged officers after summary dismissal and general prisoners. In time of war spies, retainers to the camp, persons who relieve and aid the enemy in the way specified in the statutes, are included. When a person subject to military law commits an offense he is placed in arrest or confinement. Except in cases of quarrels, frays, and disorders commanding officers have power only to put officers in arrest. An officer arrested confines himself to his quarters until his arrest is made open or its limits extended. He is not permitted to wear a sword or to visit officially his commanding or superior officer, unless directed to do so. Whenever a commanding officer places an officer in arrest and releases him without preferring charges he makes a written report to the department commander of the cause. When an officer is put in arrest for the purpose of trial, except at remote stations, the officer ordering the arrest must see that he has a copy of the charges on which he is to be tried within eight days after his arrest. Noncommissioned officers and privates to be tried by summary court are generally placed in arrest in their quarters. Privates to be tried by general court-martial are confined in the guardhouse. Confinement without trial as a punishment for an offense is forbidden. Consequent upon arrest follows a preliminary investigation as to the crime or offense charged against the prisoner and the evidence upon which it is to be supported. If the offense is one for trial by a superior court, the charges are forwarded by the

commanding officer with the statement that he has investigated them, and his opinion as to whether or not they can be sustained. When an offense is a minor one a soldier may be given punishment by extra fatigue duty, restriction of privileges, etc., provided he consents to accept such punishment in lieu of trial.

Certain various offenses against military law when committed in time of war are punishable with death. In time of peace the ordinary punishments are dishonorable discharge, confinement at hard labor, and forfeiture of pay. The maximum punishment is given only when the offense is of the worst type or when an example is necessary. In a few instances the punishments are mandatory. The purposes of military process and proceedings in respect to offenses against military law have reference always to the prevention in future of the commission of these offenses. In the military code of England prominence is given to the principle of honor, and as the life of the military community will always depend on the zealous maintenance of this professional characteristic, one of the most important purposes for which the military law exists is to preserve the honor and purity of the service.

American military law began with the War of the Revolution. Articles of war were first made for the government of the army on June 30, 1775. In April, 1806, the present military code was established. This code was derived immediately from the English military laws, and for many years the American officer was compelled to look to English treatises on military law to solve questions which arose in the course of his judicial duties. In 1864 a military law department was established by Congress, to be known as the Bureau of Military Justice. In 1883 this bureau was consolidated with the corps of the judge advocates of the army under the title of Judge Advocates Department, which it still retains. This department as now organized consists of a judge-advocate-general and 12 judge advocates, holding permanent commissions in the department. These judge advocates are stationed in time of peace at the headquarters of the several military departments into which the country is divided. In time of war they are at the headquarters of armies, field armies, and divisions. They are consultative officers and legal advisers. In important trials the direct responsibility of their prosecution is upon them. They receive and revise the proceedings of courts-martial held in their several departments, give legal opinions, and administer oaths. In the English army a judge advocate never acts as a prosecutor or witness for the prosecution. He is a helper to the court, and the prosecutor and the prisoner are entitled to his opinion on any point of law that is relevant to the trial. The judge-advocate-general is a member of Parliament, a Privy Councillor, and a responsible adviser to the crown in all cases of general courts-martial which the crown confirms.

Military law requires that before a sentence of a court can be executed it must be confirmed. In England the sentences of general courts-martial are confirmed by the King or by an officer holding a warrant from the King. In the United States the officer ordering the court or the officer commanding for the time being must approve a sentence before it can be executed. Except in certain convictions in time of war a sentence of death must be confirmed by the President. In time of peace no sentence of a court-martial di-

recting the dismissal of an officer can be executed until approved by the President. It is the duty of a confirming officer to see that the finding and sentence are legal and that the latter does not award a punishment in excess of the punishment authorized by law. Where the sentence of a court-martial imposes several punishments one or more may be approved.

The principal offenses committed by soldiers are desertion, fraudulent enlistment, disobedience to superiors, quitting or sleeping on post, drunkenness, absence without leave, selling or losing by neglect clothing or equipment, and miscellaneous offenses to the prejudice of good order and military discipline. A person in the military service is not freed from his civil obligations. He is still a citizen and amenable to the civil authority for violation of local laws. He is liable to be taxed for his real estate or household goods. He may vote at the place where he has a legal residence.

French Military Law is administered by means of regular trial and sentence before a military tribunal or by infliction by any superior or inferior punishments for mere faults. The punishments inflicted upon officers for faults against discipline are: simple arrests, rigorous arrests, reprimand from the colonel, and prison. Faults of officers too grave for disciplinary punishment are referred to courts of inquest. Councils of war, answering to the American general court-martial, take cognizance of the graver violations of military law, which can only be punished by afflictive or infamous punishments. The judgments of councils of war may be revised by councils of revision. If the latter annul the judgment referred to them, proceedings and decision are sent to a second council of war having jurisdiction in cases of judgments annulled by councils of revision. There is also a court of appeal in cases of trial and sentence for the crime of capitulation. This court is styled the Court of Cassation. Punishments in the German, Austrian, and Russian armies are similar to those in the French service.

English Military Law so nearly resembles the American as to require in this article but brief description. It is embodied in the Army Act of 1881 and is kept in operation from year to year by the passing of the Army Annual Act. It consists of a written and unwritten part. 1. The written part consists of the Army Act, rules of procedure, King's Regulations, general orders, army circulars and orders, royal warrants, and orders in council. 2. The unwritten part consists of the laws or customs of war. The sovereign has power to make articles of war, but the articles of war and the Mutiny Act have been consolidated in the Army Annual Act, and it is doubtful if the necessity for articles of war will ever arise again. The military code of England describes in detail the serious offenses against military law and prescribes the maximum punishment that can be awarded for them.

MILITARY ORDER OF FOREIGN WARS.

See FOREIGN WARS, MILITARY ORDER OF.

MILITARY POLICE. In European countries, the name given to that branch of the police force which has military as well as civil constabulary duties. In these countries the force exists in peace as well as in war. In the United States, in time of peace, there is no regular Federal military police, but they are organized as required during campaigns and during manœuvres simulating war. Selected men for such a force are detached from the army. Their status and duties are defined in the *Field Service Regulations, United States Army* (1914). The duty of military police is to enforce all police regulations in the theatre of operations and in mobilization and concentration camps. They protect the inhabitants of the country from pillage and violence and prevent excesses of all kinds, keep all roads clear, arrest all soldiers and civilian employees absent without proper authority, arrest all marauders, and collect all stragglers and hand them over to their organizations. They keep a list and description of all camp retainers and followers and watch their conduct. They take charge of all prisoners of war. They police all railroad stations, public houses, depots, and public buildings, protect telegraph and telephone lines and railways from damage, keep hostile inhabitants in order, disarm them, and prevent spying. All persons in the military service are required to assist the police when called upon to do so. Officers and enlisted men when actually performing the duty of military police wear a blue brassard on the left arm bearing the letters M. P. in white.

Although there are no Federal military police in the United States in time of peace, the State of Pennsylvania has maintained a State military mounted police force since 1909. It consists of about 300 selected men, many of them with prior service in the regular army, organized into four troops, with officers, under command of a major. The force is composed of experienced men, well paid, mounted, and armed. They guard an area of about 4500 square miles in western Pennsylvania and have proved far more successful than the local police and militia in arresting offenders and in preventing looting, disorder, and crime in time of strikes, floods, fires, and other disasters. In 1915 efforts were being made to secure a similar force for the State of New York.

A noted military police is the Royal Northwest Mounted Police of Canada. This force was organized in 1873 by the Dominion government to preserve law and order in the wilderness northwest of Lake Superior. Before the Great War of 1914 this force consisted of 55 officers and 708 selected men, distributed as follows: Alberta, 290; Saskatchewan, 390; New Manitoba (the northern and sparsely settled part), 22; Northwest Territories, 12; Yukon Territory, 49. In the summer of 1914 the force was increased by 500 men, owing to the fear of possible unrest and disorder among the 175,000 Germans and Austrians settled in the various provinces and districts patrolled by the police.

In the British army, in England, the military police consists of mounted and dismounted branches, with headquarters at Aldershot (q.v.). Their duties are similar to those of the civil police, but are confined to the soldiers of the

district in which they are stationed. In time of peace they are scattered in detachments of varying strength throughout the standing camps and large garrisons of England and Ireland. They are recruited from the regular army and are confined exclusively to noncommissioned officers and men of several years' service and unblemished record. Every member of the force is a non-commissioned officer and acts with the full authority of such. Their uniform is similar to that of the field artillery. In France similar duties are performed by the gendarmerie, a force of military police recruited from the army, but performing civil duties in time of peace. There is a legion in each army corps region, and some regions have more than one legion. The total strength is about 21,700 men, of whom about half are mounted. It is proposed to create a mobile gendarmerie, to deal with strikes and riots, so as to avoid the necessity for calling out troops on such occasions. The Garde Republicaine is also a police force and performs duties in Paris similar to those performed by the gendarmerie in the departments. Its strength is nearly 3000, of which about 800 are mounted. The military police of Germany come into active employment during war time, when each army corps mobilizes two detachments, one to accompany the corps itself and one for the line of communications. In their colonies the Germans, in addition to troops, usually maintain a military native police force officered by Germans. Police forces organized on a semimilitary basis exist throughout the British Empire. The crown colony of Hongkong has a semimilitary police force of 1173 men, of whom 164 are European, 462 Indians, and 547 Chinese. The Royal Irish Constabulary was organized in 1822 and at the present time consists of about 10,000 officers and men. This organization is famous for its efficiency and loyalty during many trying periods of Irish history. Similar bodies were organized throughout Australia, for duty in the gold-mining camps primarily and afterward to control the natives and protect isolated ranches or stations. In organization there is generally a colonel, lieutenant colonel, or major at the head, who is in turn responsible to the Minister of the Interior. Rank and title are the same as in the regular army. In South Africa the South African Mounted Riflemen, established April 1, 1913, are available for military duties whenever required and are included in the military defenses of the colony. The Nyasaland Protectorate (British Central Africa) employs a military police. They are under British officers and are charged with the duties of maintaining order and suppressing the slave traffic. The area under their jurisdiction covers 39,315 square miles and is divided into 14 districts. They also police the eastern portion of the British South Africa Chartered Company's territory, north of the Zambezi, for which they receive payment. British East Africa, besides a military force, has a police of 1735 men under 38 European officers and noncommissioned officers. The Rhodesian military police forces now include all the small bodies of men formerly engaged in the division of what is now termed Rhodesia, the corps as a whole being under the High Commissioner, as are also the forces of the Bechuanaland Protectorate and Basutoland. Similar forces were maintained throughout the German possessions in East and Southwest Africa. See PROVOST MARSHAL.

MILITARY PRISON. By law the government and control of the United States Military Prison is vested, under the Secretary of War, in the Board of Commissioners of the United States Soldiers Home, and the president of that board is required to submit to the Secretary of War annually a statement of the financial and other affairs of the prison. The board consists of the Surgeon-General, the Quartermaster-General, the Chief of Engineers, the Judge-Advocate-General, and the Governor of the Soldiers Home. The immediate administration is in the hands of army officers detailed for that duty by the Secretary of War. The United States Military Prison is divided into three branches: United States Military Prison, Fort Leavenworth, Kans.; Pacific Branch, Alcatraz Island, San Francisco harbor; Atlantic Branch, Fort Jay, Governors Island, N. Y. In addition to these prisons there are guardhouses at military posts in which general prisoners may be temporarily confined. In the United States army there are several classes of prisoners. They are designated as follows: enlisted men against whom charges have been preferred are designated as "awaiting trial"; those tried and prior to promulgation of result as "awaiting result of trial"; those serving sentences of confinement, not involving dishonorable discharge, "garrison prisoners"; officers or men sentenced to dismissal or dishonorable discharge and to terms of confinement at military posts or elsewhere as "general prisoners." So far as practicable general prisoners are kept apart from other prisoners and are the only class confined in the United States Military Prison and branches thereof. Under the law the United States Military Prison is for the confinement and reformation of military offenders against the rules, regulations, and laws for the government of the army of the United States and includes only officers and enlisted men of the army, and of the marine corps when detached for service with the army, who have been sentenced by court-martial to dismissal or dishonorable discharge and confinement. In February, 1912, was inaugurated the modern prison system of separating as far as practicable prisoners convicted of purely military offenses from those convicted of statutory or common-law crimes or misdemeanors. The general prisoners who are under sentence for purely military offenses and whose records and conduct are such as to entitle them to the privilege are now afforded an opportunity to receive a special course in military training. Under orders of the War Department, Sept. 17, 1913, four disciplinary companies were organized at the United States Military Prison, Fort Leavenworth, Kans., and one at Fort Jay, N. Y. Similar companies are to be organized at the Pacific Branch, Alcatraz Island. Bands composed of prisoners are also authorized. Prisoners granted the privilege of membership in the disciplinary companies work during half the day only, the other half being devoted to military drill and training. It is hoped by this system to reform and restore to the service a certain percentage of men now under sentence of dishonorable discharge and of forfeiture of certain rights of citizenship. Under the new plan, since September, 1913, the Judge-Advocate-General of the army has general charge, direction, and control, under the Secretary of War, of these prisons and their administration. The officers of each prison consist of a commandant, an adjutant, a quartermaster, a surgeon, a chaplain, an

executive officer, an exchange officer, an ordnance and signal officer, and such other officers as the War Department may assign. The enlisted men of the army detached for duty as prison guards are organized into companies, to which officers are assigned for the usual company duties. The number of prisoners confined at Fort Leavenworth varies between 900 and 1000; the number at Alcatraz Island, between 300 and 400; at Fort Jay, N. Y., about 100. About 1000 general prisoners are confined at military posts. In addition to the military instruction for the privileged class belonging to the disciplinary companies, the prison system provides schools, libraries, religious instruction, medical attention, and an opportunity to learn a trade.

MILITARY PUNISHMENTS. See MILITARY LAW.

MILITARY RESERVATION, UNITED STATES. A term applied to every military post, station, or other locality selected and set apart for present or future military occupation. Department commanders supervise all such reservations within their territory and are responsible that trespass and damage are prevented. They are also required to see that every consideration is given to their care, preservation, and adornment, and that every available means is employed to make them attractive homes for the army. The grounds are improved so far as possible. Where the reservations are of considerable extent or sufficiently practicable, they are stocked with game, and stringent rules made for the protection of native singing birds. Lands reserved for military use and military posts temporarily evacuated by troops are under charge of the quartermaster's department. Permanent works of defense and lands appurtenant thereto are under the direction and charge of the engineer department.

MILITARY SANITATION. See HYGIENE, *Military Hygiene.*

MILITARY SCHOOLS. See MILITARY EDUCATION; MILITARY ACADEMY, UNITED STATES.

MILITARY SCIENCE. Military science or "the art of war has for its object: first, to determine the time, place, and character of battles and conflicts so that the greatest benefits may result from victory and the least injury from defeat; second, to make one's self stronger than the enemy at the time and place of actual combat. The first of these objects is accomplished by strategy, including logistics; the second by logistics, discipline, grand and minor tactics, and military engineering. None of these branches can be practiced; or even intelligently studied separately; nor can one be rated as of higher value than the others, since ultimate success must depend upon them all. The highest strategy accomplishes nothing unless the logistic and tactical requirements for success in battle are satisfied. The best tactical arrangements and actions may result in victories entirely barren, even sometimes worse than defeat, owing to faulty strategical dispositions; while a failure in logistics will, of necessity, destroy all strategical and tactical combinations.

"To show more clearly the relations of these subdivisions to the objects of the art of war, it is only necessary to call attention to the fact that whether or not the 'greatest benefit will result from victory and the least injury from defeat' will depend upon the positions of the opposing armies with reference to each other's communications, lines of retreat, and objectives,

before and after conflicts, the moral and political effects produced by the results of battles, and the times of their occurrence. These considerations evidently involve questions of strategy, including statesmanship, both in planning campaigns and forecasting their results; and logistics, in preparing for the execution of the plans. The second object will be accomplished to a greater or less degree: first, by rapidity of concentration, giving a greater number of men at the place of actual conflict. Second, by better arms, ammunition, and supplies, better defensive arrangements, better training and discipline, or better handling of the masses or small groups, making the same, or a less, number of men stronger than the hostile force. Third, by localizing the conflict upon a point where this superiority exists. The first is a question of logistics; the second of logistics, engineering, discipline, and grand or minor tactics; and the third of grand or minor tactics, depending upon the force engaged.

"Tactics may be defined generally as the art of so handling bodies of troops, large or small, as to utilize to the fullest extent the fighting, manœuvring, and resisting capacity of every individual, weapon, and resource of all arms of the service. When applied to the combined action of large masses, made up of different arms, it is called grand tactics. When restricted to the actions of small bodies, or single arms, it is called minor tactics. This division is general and not well defined, since the two run imperceptibly into each other.

"Logistics embraces all the details of moving and supplying armies. It is essentially the province of the staff, and its different branches are apportioned to the different staff departments.

"Strategy has for its object so to inaugurate and conduct wars, campaigns, and battles as, first, to take advantage of all available means for securing success; and, second, to cause the greatest benefits to result from victory and the least injury from defeat. . . . Under the first heading it involves questions of statesmanship and diplomacy. . . . Under the second it is more frequently concerned in the moral effect to be produced by a battle, resulting, in case of victory, from the absolute losses inflicted upon the enemy or the disadvantageous positions in which he may be placed with respect to his bases of supply and lines of communications; and, in case of defeat, from the corresponding losses of our own army." (*Elements of the Art of War*, by James Mercur, Colonel, U. S. A., professor of civil and military engineering at the United States Military Academy, West Point, N. Y.)

Military engineering includes the technical work connected with the construction of permanent and field fortifications, including siege works, reconnaissance, constructing and dismantling bridges, military roads and trails, the construction, operation, and maintenance of railroads in the theatre of operations under military auspices and for military purposes, the transportation of engineering equipment such as reconnaissance instruments, the light and heavy bridge trains, intrenching tools, etc. Consult *Engineer Field Manual, United States Army.*

Logistics falls under the general head administration, as distinguished from organization and operations. The details of moving and supplying armies, or logistics, come under two very general classes of activities: the service of the interior and the service of the theatre of opera-

tions. The service of the interior is carried on by department (territorial) commanders and bureau chiefs having for this purpose general depots of supply, general hospitals, arsenals, etc. The service of the theatre of operations is carried on by the commander of the field forces and is divided into two zones: (a) the zone of the line of communications, (b) the zone of the advance. The function of the service of the interior is to supply the commander of the field forces with the means necessary for the accomplishment of his mission, i.e., to concentrate such means at the principal base of the field forces. From this principal base up to and including the advance bases in rear of the fighting divisions extends the line of communications, the commander of which is responsible to the field commander for its efficient operation and defense. From the advance bases to the fighting units is the zone of the advance, within which operate the division combat, field, ammunition, supply, sanitary, and engineer trains, designed to supply their fighting units so as to keep them always ready for action and without hampering their freedom of movement. Consult *Field Service Regulations of the United States Army* (Washington, 1914). See LOGISTICS; STRATEGY; TACTICS, MILITARY.

MILITARY SERVICE INSTITUTION OF THE UNITED STATES. An organization controlled by officers of the United States army, associated with the National Guard and others for professional improvement, the interchange of views upon military matters, and such topics in general as may be calculated to promote the military interests of the United States. In 1877 General Stanley, General Fry, General Rodenbough, and Colonel Lieber issued a circular requesting the presence of the officers in the army at a meeting to consider the practicability of forming an association similar to the Royal United Service Institution of Great Britain. About 40 officers responded, and the Institution was organized, with General Hancock as president. The headquarters of the Institution are at Governors Island, N. Y. The *Journal of the Military Service Institution*, a bimonthly, published its first number in January, 1880, and is devoted to military history and the discussion of current military questions, domestic and foreign. It is universally regarded as a publication of great international importance in its own domain. Under the management of the publication committee, essays upon military subjects, for which prizes of gold and silver medals and money are annually awarded, have been a feature. Under an agreement between the Public Library of the City of New York and the Military Service Institution, the entire collection of books and pamphlets belonging to the Institution (amounting to nearly 10,000 volumes, among which are many rare books and manuscripts), with the exception of those needed for reference, has now been placed in a section of the library at Fifth Avenue and Forty-second Street, to be known as the Military Section, duly catalogued and made available for the circulation to members of the Institution and for reference to the general public. The Institution also possesses a valuable collection of military relics and trophies, together with specimens or models after the latest war material, open to visitors.

MILITARY SIGNALING AND TELEGRAPHING. See SIGNALING AND TELEGRAPHING, MILITARY.

MILITARY SURGEON. See SURGEON, MILITARY AND NAVAL.

MILITARY SURGERY. See SURGERY, MILITARY.

MILITARY TACTICS. See TACTICS, MILITARY.

MILITARY TENURE. A form of landholding in England under the feudal system of land tenure, originally based on the obligation of the freehold tenant to render actual military duty to the crown as the service or rent due from the land so held by him. It was also known as tenure in chivalry or by knight's service. See FEUDALISM; TENURE.

MILITARY TERRITORIES OF FRENCH SUDAN. Formerly three territories comprising the eastern part of the African region previously known as French Sudan (q.v.), and extending from the eastern boundary of French Senegal and French Guinea to Lake Chad, and from the northern borders of Nigeria, Dahomey, Togo, the Gold Coast, and the Ivory Coast northward into the Sahara Desert. The region included in these territories comprised in 1915 the French colony of Upper Senegal and Niger and the Military Territory of the Niger. See FRENCH SUDAN; FRENCH WEST AFRICA; NIGER, MILITARY TERRITORY OF THE; UPPER SENEGAL AND NIGER.

MILITARY TRENCH. See TRENCH, MILITARY.

MILITARY UNIFORMS. See UNIFORMS, MILITARY AND NAVAL.

MILITARY VOLUNTEER. See VOLUNTEER, MILITARY.

MILITCHEVITCH, mē'lē-chév'itch, DJAKOV MILAN (1831-1908). A Servian ethnologist and writer on educational topics. He was born near Belgrade. Having studied theology and done some teaching, he obtained, in 1852, a state office and was made secretary to the Servian Minister of Education in 1861. In 1886 he was appointed librarian of the Belgrade National Library. Among his writings are an exhaustive topographical work, *The Principality of Servia* (1876); *Servian Peasant Life* (1867, 1894); *The Kingdom of Servia* (1884); *Letters on the History of the Servians and Bulgarians* (1858-59); *Education in America* (1863); *Letters of a Tourist* (1865); *Schools in Servia* (1868); *Lives of Famous Servians* (1888); the pedagogical periodical *Skola* (*The School*, 1868-76), and short sketches like *Furmus and Fatima* (1879) and *Winter Evenings* (1879). Militchevitch was one of the most learned and talented Servian authors of his time.

MILITELLO, mē'lē-tē'lō, IN VAL DI CATANIA. A town in the Province of Catania, Sicily, situated 25 miles southwest of Catania, with which it is connected by rail. It trades in wine, tropical fruit, and silk. Pop. (commune), 1901, 11,539; 1911, 11,232.

MILITIA, mī-līsh'ā (Lat. *militia*, military service, soldier, from *miles*, OLat. *meiles*, soldier). The entire body of male citizens liable to military duty. In England, since 1908, the organized forces are called the *regular army* and the *territorial army*. The regular army has two reserves—the *army reserve* and the *special reserve*. The latter was created out of the militia in 1907. The *territorial army*, which serves only at home in peace time and is intended primarily for home defense, amounted to 315,000 in 1914. This latter force corresponds to the *organized militia* in the

United States. In addition the colonies maintain militia forces, called citizen forces or territorial armies. Specifically the title applies to the purely defensive branch of the national military system of the countries referred to, the *mobile* and *territorial militia* of Italy and the *opolchénié* of Russia closely resembling it. The *Landwehr* and *Landsturm* of Germany and Austria and the *territorial army* of France may also be regarded as the militia equivalent, the service, however, being compulsory instead of voluntary as in England and the United States. In the United States the system differs somewhat from the English in that it is not a Federal or national force, unless called into the service of the Federal government or unless accepted as volunteers by the President during the existence of war or when war is imminent under the provisions of the Act of Congress approved April 25, 1914. When the militia, as such, is called into the service of the United States it must serve during the period specified by the President in the call for militia, but individuals cannot be held beyond the period of the existing State commission or enlistment, usually two or three years. As militia it cannot serve without the territorial limits of the United States. If the militia, however, changes its status to that of volunteers and is accepted as such under the Volunteer Act of April 25, 1914, such troops then serve, unless sooner discharged, for a period of four years, and may be employed beyond the territorial limits of the United States. The act quoted is regarded as one of great moment in that it affords a means of changing the State militia into a true Federal force subject to all the rules and regulations of the regular army except that no reserve service is required. From 1775 to 1783 the bulk of the Federal armies consisted of State troops, a condition which continued to exist long after the Revolution itself. The United States militia consists of every able-bodied male citizen of the respective States, Territories, and the District of Columbia, and every able-bodied citizen of foreign birth who has declared his intention to become a citizen, who is more than 18 and less than 45 years of age. It is divided into two classes—the organized militia, known as the national guards of the State, Territory, or District of Columbia, or by such other designation as may be given them by the laws of the respective States or Territories, and the remainder known as the reserve militia. It is impracticable of course for the President to call out this reserve militia, as it does not possess a military organization. The organization, armament, and discipline are the same as those prescribed for the regular and volunteer armies of the United States, but the effectiveness of the organized militia as a military force is seriously handicapped by the constitutional provisions which reserve to the State the appointment of all officers in peace and war, the training and government of the forces when not in the service of the United States, and the limited instruction provided by the State authorities in peace. The officers are usually elected by the men and appointed by the governor. The President may call out, for a period specified by him, such numbers of the militia of the States, Territories, or District of Columbia as he may deem necessary "to suppress insurrection, repel invasion, or to execute the laws of the Union," but for no other purpose. During their period of service

they become subject to the same rules and articles of war as the regular forces, except that they cannot be called upon to serve outside the United States. Experience in using State militia as a Federal force has always proved unsatisfactory. In 1915 legislation for the creation of a national militia was under consideration. Each State and Territory and the District of Columbia has an adjutant general, who is charged with the duties as prescribed by the State and the rendering of regular reports to the Secretary of War regarding the strength, condition, etc., of the organized militia of the State to which he belongs. See *Army* under UNITED STATES.

The table on page 668 is an abstract of the militia force of the United States (organized), according to the report of the Chief of Division of Militia Affairs, War Department.

The militia of Great Britain was a constitutional force raised under authority of Parliament for national defense only. It could not be used on foreign service without its consent and the authority of Parliament. Before the Norman Conquest rents for land were paid in body service, the able-bodied men of each family bearing arms in numbers proportionate to the land held by the family. This system is attributed to the Saxon King Alfred. The country was organized into dukedoms, hundreds, tithings (ten tithings making the hundred), and families, the number of families in a tithing varying with the necessities of the times. After the decisive battle of Hastings (1066) the *fyrd*, as the militia was then called, ceased to exist officially, although continuing to give the Normans considerable trouble. The national exigencies during the Seven Years' War rendered imperative the reorganization of 1757, since which period more attention has been devoted to it. In 1871 the War Office assumed control and the county authorities ceased to have any active interest in it other than the right to nominate officers. In 1906 it was a part of the military territorial system, two or more local militia battalions being attached to each territorial district and forming the third, fourth, or fifth battalion (as the case might be) of the regular regiments to which they were attached. In 1908 the militia was abolished and converted into the special reserve and territorial force. See *Army* under UNITED KINGDOM.

In Russia what is now the *opolchénié* was originally a simple militia, which was reorganized in 1888 and again in 1891, when the period of service was changed from 40 to 43 years for the soldiers and from 50 to 55 for the officers. Service in the Russian army, 1914, is as follows: from the twentieth to the forty-third year, divided into two classes—service in the active army and its reserve for 18 years, service in the *opolchénié* or territorial army for 5 years. The *opolchénié* is divided into two "bans," or levies, (1) trained men who have passed through the active army and the annual surplus of young men, (2) the *levy en masse*, containing all those exempted from actual service, whether as students, only sons, or those not up to physical standards, and also the older classes of the surplus men who have all had a certain amount of training. This second "ban" corresponds to the United States reserve or unorganized militia.

Service in the Italian army, 1914, is for 19 years. Commencing at the age of 20, there are three classes, as follows: first, those in the permanent army; second, those in the permanent

Total strength of militia 1,148,114

army but with "unlimited leave"; third, those exempted from active service, who are assigned to the territorial militia. The time is spent as follows: 2 years with the colors, 6 years in the reserve, 4 years in the mobile militia, 7 years in the territorial militia, total 19 years, thus completing service at the age of 39.

Service in the French army, 1914, is from the age of 20 to 48. In the first line or active army, 3 years; in the reserve for that army, 11 years; in the territorial army, 7 years; in the territorial reserve, 7 years; total service 28 years, ending in the forty-eighth year.

In Switzerland the entire army, comprising as it does every able-bodied citizen, is a militia. Switzerland is unique in that it has no permanent or standing army, depending solely on its national militia. Service extends from the seventeenth to the forty-eighth year, actual service commencing at 20. Periods (1914) are

mares, to rub off). The liquid secreted by the mammary glands of all mammals and used primarily to nourish their young. From the earliest time it has been esteemed an important and necessary article of food and many hidden virtues were ascribed to it by the ancients. Its exact composition continued long unknown, and until the beginning of the seventeenth century fat, casein, and whey were the only constituents recognized. In the early part of the eighteenth century Leeuwenhoek discovered the microscopical characteristics of milk, and about the same time Boerhaave made a qualitative examination. The first quantitative analysis of milk recorded was made in 1737 by Geoffrey, who determined with considerable accuracy the casein, milk sugar, and mineral matter.

The milk from different animals varies considerably in composition, as shown in the following table:

COMPOSITION OF MILK

KIND	Water	Total solids	IN TOTAL SOLIDS				
			Fat	Casein	Albumin	Milk sugar	Ash
			Per cent	Per cent	Per cent	Per cent	Per cent
Woman	87.4	12.6	3.8	1.0	1.3	6.2	0.3
Cow	87.2	12.8	3.7	3.0	0.5	4.9	0.7
Buffalo	81.4	18.6	7.5	5.8	0.3	4.1	0.9
Goat	85.7	14.3	4.8	3.2	1.1	4.4	0.8

Llama	86.5	13.5	3.2	3.0	0.9	5.6	0.8
Mare	91.5	8.5	1.2	1.2	0.1	5.7	0.3
Ass	89.6	10.4	1.6	0.7	1.6	6.0	0.5
Camel	86.6	13.4	3.1	4.6	4.0	5.6	0.7
Bov	84.0	16.0	4.0	7.2	7.2	3.1	1.1
Elephant	67.9	32.1	19.6	3.1	3.1	8.8	0.6
Porpoise	41.1	58.9	45.8	11.2	11.2	1.3	0.7
Dog	75.4	24.6	9.6	6.1	5.1	3.1	0.7
Cat	82.1	17.9	3.3	3.1	6.0	4.9	0.6

as follows: 12 years in the first line, called the Auszug or Elite; 8 in the Landwehr; 8 in the Landsturm. A soldier has from 65 to 90 days' training of 11 days each for seven years, when all below the rank of sergeant are excused from further attendance. The Landwehr are called out only once for 11 days. It is thus seen that this is a true militia—first trained and then returned to civil pursuits, subject to call when needed—and that there is no standing or permanent army as in the other countries just referred to. This militia service, however, is compulsory and universal. See CONSCRIPTION; LANDSTURM; LANDWEHR; NATIONAL GUARD; VOLUNTEER, MILITARY; and section *Army* under the different countries.

MILKUM, mil'q-um. A skin disease known also as grutum. It is characterized by the formation of small, round, noninflammatory elevations situated immediately beneath the epidermis and consisting of sebaceous matter. These bodies are distributed mainly on the eyelids, forehead, and face, occur especially in elderly people, and may in time undergo calcification. Colloid milium is a rare form of the disease in which the bridge of the nose, forehead, and cheeks present minute shining lesions of a pale lemon color.

MILK (AS. *meole*, *meoluc*, Goth. *miluks*, OHG. *miluk*, Ger. *Milch*; connected with AS. *melcan*, OHG. *melchan*, Ger. *melken*, Lat. *mulgere*, Gk. *μῆλαια*, *amelgein*, OChurch Slav. *mĕlati*, Lith. *milati*, to milk, Skt. *varj*, Av.

The above are general averages of a greater or less number of analyses, depending upon the kind of milk animal, each kind of which gives milk that varies considerably with the individual as well as with the species. There is, furthermore, some difficulty in arriving at a general average for any kind of mammal, since normal milk is obtained with difficulty from animals unaccustomed to being milked.

Properties of Cows' Milk. Since, in general properties and composition, cows' milk is typical of all milks, is of chief commercial interest, and has been studied much more in detail, it will be the main subject of this article. The milk secreted immediately after parturition is termed *colostrum* (q.v.), or *beastings*, and differs considerably from normal milk in both physical and chemical characters. Milk from which the fat has been removed by skimming or by the separator is called skim milk (q.v.), and the residue left after churning cream is known as buttermilk (q.v.). Whey (q.v.) is the liquid remaining after the curd of the milk has been separated.

Cows' milk is an opaque, whitish liquid, sometimes faintly yellow or bluish, with a slight alkaline reaction and a sweetish taste when fresh. It is heavier than water, its specific gravity ranging usually from 1.029 to 1.035, the average for mixed milk being about 1.032. By removing the fat (skimming the cream) the specific gravity is raised and by adding water it is lowered. This is the basis of a simple, but (when taken alone) unreliable, test of the qual-

ity of milk and of the practice of skimming. Chemically, milk consists of an aqueous solution of milk sugar, casein, albumin, and ash, with the fat in suspension, forming an emulsion. The water and the constituents dissolved in it constitute the milk serum, and the constituents (i.e., the dry matter) minus the water are designated total solids. The proportion of total solids is a general indication of the richness of the milk. Among the solids the chief importance attaches to the fat. First, it is the measure of the value of milk for butter making, and to a very great extent for cheese making also; second, it is the constituent which more than any other gives milk its appearance of richness; third, it fluctuates more widely than any other constituent. Milk fat is a familiar substance in the form of butter, which contains about 85 per cent of fat, some water, salt, and casein. The fat in milk is in the form of minute globules held in suspension, and on standing it rises to the surface as cream (q.v.), which contains some of the other constituents in smaller proportion. The globules may be readily seen by means of a microscope. For a long time fat globules were believed to be surrounded by a membrane or proteid coating, which was destroyed by churning the cream and thus allowed the fat to unite into a solid mass. This view is still held by some, but the prevailing belief at present is that the globules are free and owe their spherical form to the surface tension. The globules vary greatly in size, being from $\frac{1}{1000}$ to $\frac{1}{100}$ of an inch in diameter. A pint of average milk has been estimated to contain not far from a million globules. The size of the globules varies with the period of lactation, diminishing towards the close, and to some extent with the breed and the individual. The globules in the Jersey and Guernsey milk are relatively large; in Holstein milk very small. The large globules rise more rapidly, and milk containing them creams more readily and completely.

Milk fat is a pale yellow substance consisting of a mixture of the glycerides of eight or more fatty acids. Of these olein constitutes about 35 per cent, palmitin 25.7, myristin 20, laurin 7.5, butyric 3.85, caprin 3.6 per cent, and the remainder is principally caprylin and stearin. By the action of caustic alkali these glycerides are broken up into their respective fatty acids and glycerin, and a certain relatively small proportion of these, including the butyric, caproic, and caprylic acids, are volatile. The characteristic flavor and aroma of milk and butter are due largely to butyric, and this decomposes readily, forming butyric acid, which is evident in rancid or "frowy" butter. The chief nitrogenous or albuminoid constituent of milk is casein, which is of prime importance in cheese making. It is coagulated by rennet and by acids, and this is what gives sour milk its thick curdled appearance. The acid developed in souring precipitates the casein, which gradually separates from the soluble constituents, inclosing much of the fat. Casein is held in solution in milk by the presence of lime salts, and lime water causes it when curdled to separate in a much more finely divided condition. The albumin of milk is not curdled by acids or rennet, but is acted upon by heat. Fibrin, similar to that of blood, globulin, nuclein, and several other nitrogenous bodies, have been found in milk in small quantities, but are of little importance. The sugar in milk, chemically known as lactose, is not so sweet as

cane sugar. It is in solution. The ash of milk consists of a mixture of a number of salts, but is composed principally of the phosphates of lime and potash, the chlorides of potash and soda, and small amounts of phosphate of iron and magnesia. Some of the phosphate of lime appears to be associated with the casein, which also contains some sulphur. Most of the salts are in solution. Besides the constituents named, milk contains normally a coloring matter, a trace of citric acid, urea, and several other bodies. The fat and the albumin of milk are the most variable constituents, the ash and the sugar the least so. The casein bears a quite constant ratio to the fat, rising and falling with it.

The natural yellow color of milk, as Eckle has found, is due to the pigments carotin and xanthophyll, constituents of green plants, which are taken up from the feed and secreted in the milk fat.

Variations in Milk. The richness of milk is to a certain extent an individual characteristic; i.e., some individuals normally give rich milk, while others, for no apparent reason, give milk containing large percentages of water. The richness of milk has been increased by domestication, care, and breeding, and certain breeds of cows, sheep, goats, etc., have been produced which give a characteristically rich milk. The quality also varies with the stage of lactation. The milk given early in the lactation period is usually poorer than that secreted later, and grows richer towards the close of the period until the animal "goes dry." Young animals usually give poorer milk and less of it than after the third or fourth parturition, and the milk from the first part of any milking is poorer than the last part, or "strippings." The kind of food has little effect on the composition of milk, provided it is wholesome and the amount sufficient. Food influences the proportion of the different fatty acids composing the fat, and so has an effect on the hardness and other qualities of butter. But the rather prevalent notion that the milk fat can be permanently increased by feeding has been shown by much careful investigation to be a fallacy. Little is known of the physiological processes by which the constituents of the food are transformed into milk constituents. In some cases there appears to be a direct transmission of the constituents from the food to the milk, as is noticeable when cows eat garlic, onions, etc. The experiments of Jordan at the New York State Experiment Station have shown that milk fat is not derived solely from the fat of the food, for cows fed upon food from which the fats were practically completely extracted continued to secrete milk of normal composition for long periods, and, judging from the maintenance of their weight, did not draw upon their body fat to supply this ingredient. Under the conditions of the experiments the carbohydrates seemed to be utilized to some extent in the elaboration of milk fat. The more the process of milk secretion is understood the more apparent it becomes that richness and the volume of the yield are individual characters, and if cows have a tendency to give poor milk no amount of feeding will overcome it. The remedy lies in getting better cows. For general statements regarding the composition of the milk of different breeds of cows, see CATTLE.

As an illustration of the variation of the milk of ordinary cows of mixed breeding the data

obtained by Van Slyke in New York from the analysis of the mixed milk of 15,000 cows each month from May to October may be cited. The total solids ranged from 11.17 to 13.91 and averaged 12.67 per cent, and the fat from 3.04 to 4.06 and averaged 3.75 per cent. The content of total solids and of fat was lowest during the summer months and increased in the fall. In the analysis of over 3000 samples of milk at the Massachusetts Experiment Station the total solids varied from 10.02 to 19.55 and averaged 13.57 per cent, and the fat from 1.5 to 10.70 and averaged 4.32 per cent. The analysis of 800 samples made at the experiment stations in different parts of the country varied in total solids from 9.3 to 19.7 per cent, averaging 12.8 per cent, and in fat from 1.7 to 6.5, averaging 3.7 per cent.

Milk Fermentations. Milk is subject to a great variety of fermentations, for it is a favorable medium for the growth of many kinds of bacteria, yeasts, and other fungi which cause numerous changes in its constituents. Thus, while one class of organisms curdles milk by the production of lactic acid, another class gives it an alkaline reaction, at the same time curdling it; others impart to it a deep blue, violet, yellow, green, or red color, by the production of pigments in the milk; others give it a bitter or other unpleasant taste; another class produces alcohol from the milk sugar, and is taken advantage of in the preparation of such beverages as kumiss and kefir (qq.v.), and still others cause putrefaction. The most common and familiar change is the souring of milk, due usually to the action of lactic-acid bacteria. Under ordinary conditions normal milk nearly always undergoes some sort of lactic fermentation on standing. The production of lactic acid soon curdles the milk and obscures all other forms of fermentation, and the acid stops the growth of other bacteria, so that no subsequent effects are usually seen. The popular belief that the electricity in the air during thunderstorms sours milk appears to be unfounded, but its rapid souring at such times is due to the climatic conditions prevailing, which hasten bacterial growth. The same difficulty in keeping milk is experienced during very hot weather. Curdling is not always due to the formation of acid; milk apparently sour may have no acid taste. In such cases the cause is due to alkaline fermentation, induced by another class of organisms. The milk becomes coagulated into a soft slimy mass, which is usually bitter and has an alkaline or neutral reaction. Ordinarily this form of fermentation is not very apparent, as the organisms causing it grow slowly and the lactic-acid organisms get the start of them. The organisms which produce butyric acid in milk attack and decompose the fats, giving a rancid odor. In the ordinary handling of milk the latter are of little importance, but it is supposed that they have an important effect upon the keeping properties of butter. Several organisms have been described which impart a bitter taste to milk, due, in some cases at least, to the production of a bitter principle. Milk which has been boiled is likely to develop a bitter taste, for the reason that the heating kills the lactic-acid germs, while the bacteria causing the bitter taste usually possess endospores which are not destroyed by heat and so have a clear field for action. A slimy fermentation of milk is a somewhat common occurrence, and occasionally pro-

duces great trouble in dairies, since it destroys the milk for all ordinary uses. Such milk becomes thick and ropy, will not cream, cannot be churned, and is unfit for drinking. It may be caused by a variety of organisms. There are several forms of the trouble. One known as the "lange wei" (long or stringy whey) is made use of in the manufacture of Edam cheese in Holland, to control the gassy fermentation of the curd.

In addition to the fermentations and other changes in milk due to microorganisms, rennet, an unorganized ferment obtained from the stomach of the calf and from some plants, ferments milk, causing it to curdle. This ferment is employed in cheese making to produce the curd. Babcock and Russell have discovered an unorganized ferment termed "galactase" in milk, which they believe to be a normal and inherent constituent, and which is active in the ripening of cheese, causing the characteristic changes in the green cheese which make it suitable for eating.

The chief sources of bacteria in milk are the cow herself, the milker, the dust of the stable, and the dairy utensils. It has long been believed that pure milk drawn from a healthy cow contains no bacteria and that all bacterial contamination of the milk comes from external sources. However, the large calibre of the milk duct makes it possible for bacteria to enter it and grow to a considerable extent, so that it becomes a matter of extreme difficulty to obtain milk from the cow, even with the greatest precautions, which shall not be contaminated. The hairs of the cow are always covered with dirt and dust, and the air of the stable is charged with dust from the fodder and bedding material, so that it is impossible to prevent some dirt from falling into the milk pail. Thus large numbers of bacteria, especially in poorly ventilated stables, reach the milk. Any dirt upon the hands or clothing of the milker will have abundant chance to get into the milk pails and cans. The milk vessels themselves are an important source of contamination, the corners and creases retaining bacteria which have not been removed or killed by the washing. The warm milk furnishes favorable conditions for the growth of these microorganisms which have gained access and which for a time multiply rapidly.

Several species of bacteria classed as pathogenic organisms are capable of living or even increasing in milk, but since they do not ferment the milk or alter its appearance sufficiently to be detected by a physical examination, their presence is not readily determined. Except in very rare instances the milk becomes contaminated after it has been drawn and in practically all these cases the cause of contamination is some form of uncleanness, either of the stables, the water, the utensils, or the attendants. It is gratifying to know, however, that through the efforts of the United States Department of Agriculture, the agricultural experiment stations, and the dairymen themselves, the sanitary management of dairies is being constantly improved, and through the vigilance of State-appointed dairy inspectors unsanitary conditions are corrected as soon as discovered.

Milk Adulteration and Control. The milk supply of towns and cities has for many years been regulated by laws and ordinances and subjected to inspection. The object of this was formerly to prevent adulteration, but of recent

years the inspection has often extended to the herds and stables and all that relates to the milk trade. It has come to be realized that such factors as the health of the cows, hygienic condition of the stables, and cleanliness in the handling of the milk are quite as essential to pure wholesome milk as freedom from adulteration. Hence the veterinary inspection, which has been introduced in some cities, should be extended. Milk is most often tampered with by removing a part of the cream or by diluting it with water or skim milk. Coloring matter is sometimes added to make it appear richer, but the addition of chalk, burnt sugar, or similar substances is now rare. Preservatives, such as formaldehyde, borax, and salicylic acid, are frequently added to prevent milk souring. Opinions differ as to the injuriousness of these preservatives, but their use is generally condemned on the ground that they are unnecessary in pure milk and that they are a cloak for insanitary practices in the dairy. The standards for milk adopted by different States vary from 11.5 to 13 per cent for total solids and from 2.5 to 3.5 per cent for fat. Milk found below these standards is held to be adulterated. A standard of 12.5 per cent of total solids and at least 3 per cent of fat seems fair.

Various means of testing milk as to its quality have been suggested from time to time. Of these the lactometer is the simplest and has been extensively used by milk inspectors who have a large number of samples to examine daily to detect watering or skimming. It is a form of hydrometer, and shows the specific gravity of milk upon a graduated scale. But there are so many factors that affect the specific gravity, and this may vary so much in pure milk, that the lactometer reading is only an indication and cannot be relied upon as final. The most reliable and satisfactory of the simple milk tests is the Babcock test, which has come into very widespread use in the milk inspection of towns and cities and in determining the fat content of milk as a basis for paying for the product at creameries. (See CREAMERY; BUTTER MAKING.) This test is made in a special bottle having a narrow graduated neck. A definite quantity of milk is treated in the bottle with sulphuric acid to dissolve the curd and set the fat free. The bottle is then whirled rapidly in a centrifugal apparatus for a few minutes, to aid in separating the fat; hot water is added to bring the fat up into the neck, after which the bottle is whirled a second time and the column of fat read off on the graduated scale. The reading gives the percentage of fat without calculation. A large number of samples may be tested simultaneously, and the method has been shown to be very accurate after a little practice. It shows only the fat content, which is the common measure of richness; but from it and the lactometer reading the total solids and other constituents can be calculated. A bacteriological examination is rarely made in connection with the ordinary milk inspection.

Milk as Food. Milk is peculiarly adapted to be a food for man principally because it contains the four classes of nutrients—protein, fat, carbohydrates, and mineral matter—in more nearly the proper proportions to serve as a complete food than perhaps any other single food material. (See FOOD.) A quart of milk contains about four ounces of nutritive material, or about the same as three-quarters of a pound of beef or as

six ounces of bread. Although these quantities of milk, beef, and bread supply like amounts of total nutrients, their nutritive values are not the same. In other words, they would not be equally useful as food, owing to the relative proportion in which the nutrients are present. Protein, fat, and carbohydrates occur in milk in about equal proportions. The chief nutrients in bread are carbohydrates and protein, and in meat protein and fat. Either milk or bread eaten alone would make a better balanced food for man than meat. In general, milk and cream together furnish to the diet of average American families about 20 per cent of the total food, 11 per cent of the total protein and also of the total fat, and about 5 per cent of the total carbohydrates. Dairy products (milk, cheese, butter, and cream) furnish over 22 per cent of the total food, 12 per cent of the protein, 32 per cent of the fat, and 5 per cent of the carbohydrates.

As regards the digestibility of all its ingredients, milk is one of the most digestible of animal foods. It has been found that on an average an adult digests about 97 per cent of the protein, 95 per cent of the fat, and 98 per cent of the carbohydrates of milk. According to American experiments, a child one year old eating milk digests on an average only about 90 per cent of the protein, 96 per cent of the fat, and 86 per cent of the carbohydrates of cows' milk. When milk is taken into the stomach it is speedily curdled by the action of the pepsin and acid of the gastric juice. When eaten alone or in large quantities the casein gathers in large lumps, which in some persons may be difficult to digest. This is particularly the case with infants and with adults whose digestion is weak. The casein of human milk is precipitated in more flocculent form than that of cows' milk, and is thus more easily digested and does not cause irritation. Lime, which tends to prevent the curdling of the casein of cows' milk in lumps, is frequently added as lime water to milk that is to be fed to infants or to adults of delicate digestion. The results of experiments upon the effect of cooking milk are conflicting. The more common experience seems to indicate that cooking or heating the milk renders it more difficult to digest. Some persons, however, cannot take fresh milk with comfort, but can digest boiled milk.

Milk is often said to be a perfect food. It is so for the young of the species of animal producing it, but there are three reasons why it cannot be considered a perfect food for adults. 1. The proportion of water is so large that great quantities (from 4 to 5 quarts) would have to be consumed each day in order to obtain the necessary nutrients. 2. The protein is present in rather large quantities as compared with the fats and carbohydrates. Thus, the milk necessary to furnish the 0.28 pound of protein per day, estimated to be required by a man at moderately active work, would yield only 2700 calories of energy, while milk in sufficient quantity to furnish the 3400 calories estimated as necessary would yield 0.34 pound of protein. 3. It is a well-recognized fact that the digestive functions require that food itself, besides the water taken with it, shall have a certain bulk. Cattle cannot generally be maintained in health upon a condensed ration such as grain; they seem to require a certain distention of the stomach, such as is brought about by the fibre (cellulose or woody matter) of grass or hay. It

like manner it seems desirable that man should have a certain amount of bulky material to produce distention or to promote peristaltic action of the intestines, or for other purposes not well understood. Of course, the nutritive constituents of milk, considered separately, are highly concentrated foods. While, therefore, milk alone cannot be considered as a perfect diet for adults, it is of special value as a food for invalids, because it is, as a rule, easily taken, easily digested, and does not generally irritate the alimentary canal. Furthermore, a milk diet is more readily under the control of the physician both as regards quantity and quality than a mixed diet is. If for any reason a child cannot be nourished on mother's milk, the most useful substitute is modified cows' milk. Various infant foods and milk substitutes have been proposed and are sold under divers trade names.

As a food for adults cows' milk is unusually well adapted for use in connection with other foods, either in its uncooked form in tea and coffee, as a beverage, as bread and milk, etc., or incorporated and cooked with other materials. In many culinary products it can be used instead of water. Analysis of bread, rolls, etc., made with milk would show about one-tenth more protein and one-twentieth more fuel value than bread made with water. Milk is very generally used in many kinds of cake and pastry and in custards. Where desirable from economical reasons, or as a means of increasing the proportional amount of protein in a diet, skim milk can be advantageously substituted for whole milk. At the price ordinarily paid in our large cities milk is a food of reasonable cheapness, and at the prices prevailing in small cities and country towns it is an economical food. Condensed milk is a more nutritious food, pound for pound, than fresh milk, since it has been concentrated by evaporation. It is, however, usually diluted before it is used, and then approximates fresh milk more or less closely in composition and food value. If the condensed milk contains added sugar its carbohydrate content is, of course, higher than that of unsweetened condensed milk, and when diluted, proportionally higher than that of fresh milk. Cream, which contains the greater part of the fat of the milk, as well as some protein and carbohydrates, is chiefly valuable in the diet as a source of energy. Curds obtained in the manufacture of cheese are eaten to a limited extent. They consist quite largely of the casein of milk, and hence supply the body with building material as well as energy. Butter and cheese (q.v.), the principal milk products used as food, are of great importance as articles of diet.

There are at least four distinct fermented beverages prepared from milk—kefir (q.v.), kumiss (q.v.), matzoon (q.v.), and leben. They are properly classed as food beverages and are often recommended for the sick and for convalescents. A number of special foods are made from the dry casein of milk and are used to a considerable extent by physicians to supply protein in a readily digestible form. The albuminoids of milk are used in the manufacture of egg substitutes. Milk sugar prepared from whey is an important article of diet for invalids and is used in medicine and in other ways. See MILK PRODUCTION.

Condensed Milk is the fresh milk of cows from which a considerable part of the water has been removed by evaporation to a semifluid

condition, and to which sugar is usually, although not always, added to aid in preserving it. Both the sweetened and the unsweetened products are put up in hermetically sealed tin cans, or in bulk for the use of bakers, confectioners, and ice-cream manufacturers. Originally the unsweetened milk was sold under the name of evaporated cream, but this is forbidden under the pure-food laws.

The process of making condensed milk was invented by an American, Gail Borden, and patented in 1856. In this process the milk was concentrated by heating in a partial vacuum under a low degree of heat, and this principle is still employed in making the great bulk of condensed milk in the United States and Europe, in spite of numerous other processes. The product is made at factories, which require to be equipped with expensive machinery and need a large milk supply, preferably 15,000 pounds a day.

In 1909 the United States Census reported the production of condensed milk at nearly half a billion pounds a year, valued at \$33,583,129. In 1914 the total number of condenseries in the United States was estimated at nearly 250. The industry has made rapid progress in Canada, Austria, New Zealand, Switzerland, Germany, Great Britain, Holland, Sweden, Norway, Russia, Japan, and India. The standard for condensed milk is about 28 per cent of total solids.

Milk Powder, Desiccated Milk, or Dehydrated Milk is made by evaporating milk, whole or skimmed, to dryness. The difference between the product and condensed milk is mainly in degree of concentration. The industry has developed rapidly in recent years. The bulk of the powder is made from skimmed milk, as that from whole milk becomes rancid rapidly. There are several processes. In one of the most successful the milk is condensed in a vacuum pan to about one-third its volume and then sprayed into a current of hot air in an evaporating chamber, where it rapidly parts with its vapor, the milk solids falling to the bottom as a finely divided powder. The powder contains 5 to 8 per cent of water and from 10 to over 20 per cent of fat, according to the process and the kind of milk used. The skim-milk product has about 37 per cent of proteids and 46 per cent of milk sugar. This product will keep indefinitely if not allowed to become moist. Vast quantities of milk powder are used in making milk chocolate and by bakers and confectioners. The proteids must be in soluble form to make the powder a satisfactory substitute for milk when dissolved in water. This is secured by keeping down the temperature of evaporation to prevent change in these bodies.

Bibliography. The literature of milk is extensive. In addition to the publications of the United States Department of Agriculture and the bulletins of the various experiment stations, the following works may be mentioned: C. M. Aikman, *Milk: Its Nature and Composition: A Handbook on the Chemistry and Bacteriology of Milk, Butter, and Cheese* (New York, 1895); W. Fleischmann, *The Book of the Dairy: A Manual of the Science and Practice of Dairy Work*, translated by Aikman and Wright (London, 1896); Hogan, *How to Feed Children* (Philadelphia, 1896); Holt, *Diseases of Infancy* (New York, 1899); Monrad, *Pasteurization and Milk Preservation* (Winnetka, Ill., 1901); De Rothschild, *Bibliographia Lactaria* (Paris,

1901), containing 8375 titles; H. D. Chapin, *Theory and Practice of Infant Feeding* (New York, 1902); H. W. Conn, *Bacteria in Milk and its Products* (Philadelphia, 1903); R. Lez , *Les industries du lait* (Paris, 1904); E. F. Willoughby, *Milk: Its Production and Uses* (Philadelphia, 1905); L. L. van Slyke, *Modern Methods of Testing Milk and its Products* (New York, 1906); H. Snyder, *Dairy Chemistry* (ib., 1906); Russell and Hastings, *Outlines of Dairy Bacteriology* (9th ed., Madison, Wis., 1910); W. G. Savage, *Milk and the Public Health* (London, 1912); Farrington and Wall, *Testing Milk and its Products* (Madison, Wis., 1912); H. H. Wing, *Milk and its Products* (rev. ed., New York, 1913), containing a bibliography; Levi Wells, "Condensed and Desiccated Milk," in *United States Department of Agriculture, Yearbook, 1912* (Washington, 1913); O. F. Hunziker, *Condensed Milk and Milk Powder* (Lafayette, Ind., 1914); R. T. Mohan, "Manufacture of Condensed Milk, Milk Powders, Casein, etc.," in *Society of Chemical Industry, Journal*, vol. xxxiv (London, 1915).

MILK, CONDENSED. See MILK.

MILK, FERMENTED BEVERAGES. See KEFIR; KUMISS; MATZOON.

MILK CURE. The treatment of disease in the adult by the use of milk as a diet. In the milk cure all other food and drink are suspended for a time. Acting upon the information that milk requires about three hours for complete digestion, four ounces of milk are taken by the patient every three hours, beginning on rising in the morning. In a few days one or two tumblerfuls are taken at a time in place of the smaller quantity. Usually a patient takes two quarts a day; in some cases the total amount reaches five quarts. It is generally administered warm. In cases of stomachic or intestinal disorders the milk is allowed to stand for 24 hours and is then skimmed before being administered. Lime water, in the proportion of one-fourth of the bulk, overcomes the patient's repugnance to the diet and renders it more easy of digestion. Or the milk may be flavored with coffee, cocoa, salt, or caramel. After two or three weeks of strict milk diet it is advised that a little stale bread be added three times a day. A week later about two tablespoonfuls of rice or a little arrow-root is added. At the fifth week a chop is given once a day, and a few days later two chops a day are allowed. At the end of the sixth week full meals of various foods are resumed, milk continuing to be a principal part of the diet. Coffee, or aloes, or laxative mineral water is employed to overcome the constipation attendant upon a milk diet in adults.

The milk cure is successful in some cases of dyspepsia, gastric ulcer, chronic intestinal indigestion, enteralgia, chronic diarrhoea, and dysentery. In the treatment of ascites of hepatic origin it has been used since the days of Hippocrates, who refers to it. It has also proved efficacious in kidney and cardiac diseases and in rheumatic and gouty affections.

MILK FEVER, IN WOMEN. A slight, transient rise in temperature, preceded by chilly sensations, attending the establishment of the milk secretion in parturient women. Antisepsis and rational feeding have largely done away with milk fever, some modern authorities even doubting its existence. The older writers describe a condition in which the breasts become swollen, reddened, and tender, with a diminution in the

lacteal discharge. It is seen occasionally in well-marked form in debilitated women, in whom a distinct chill, followed by a sharp rise in temperature and sweating, occurs. The condition requires no treatment, as a rule, except purpation.

MILK FEVER, PARTURIENT APOPLEXY, or PARTURIENT PARESIS. An afebrile disease of cows, especially good milkers of improved breeds in good condition, which occurs only at or near the time of calving. Parturition and plethora are preëminently the causes of the disease. Predisposing causes include confinement in the stall, high temperature, electrical disturbances, constipation, and mature age. The latest work indicates that the main cause of the disease is the production of poisonous metabolic products by secreting cells of the follicles of the udder, which act on the brain and central nervous system. The disease rarely follows the first and second calvings. One attack seems to predispose towards another. It appears in two forms—congestive and torpid. In the congestive form the cow suddenly becomes dull, allows the head to droop, staggers in attempting to walk, falls, and lies either on the breastbone, with the head turned around to the side and resting on the muzzle, or stretched out on the side. The pupil of the eye is dilated and the head and horns are hot; the bowels and bladder soon become torpid or completely paralyzed and fail to operate unless recovery takes place. In the torpid form there is no marked fever and no congestion of the head. The animal slowly becomes drowsy and weakened, falls down, and, unless relieved, finally succumbs. Insensibility is a pronounced symptom in the later stages of both forms.

Preventive measures include a spare diet for a week before calving and at least four days after, a free access to salt and water, a dose of Epsom salt (one to two pounds) 12 to 24 hours before calving is due, and the postponing of the drawing of any milk from the udder for 12 to 24 hours after calving.

The treatment of milk fever has been completely revolutionized by the investigations of Schmidt of Denmark, which have resulted in the universal adoption of the method of inflating the udder with oxygen or filtered air. Under this treatment the mortality in milk fever in the cow has dropped from 60 to 75 per cent to less than 5 per cent in those cases which are promptly attended and in which no medicine has been administered by mouth. Drenching of cows suffering from this disease should be rigidly abstained from, since the mortality which follows is exceedingly high, due to portions of the drench passing down the trachea into the lungs. As a prophylactic measure, in case there appears to be any danger of an attack of milk fever, it is now uniformly advised that the udder be inflated at once.

MILKFISH. A large, silvery, herring-like fish of the genus *Chanos* and family Hiodontidae, which inhabits the warmer parts of the Pacific. One well-known species (*Chanos chanos*), from 2 to 5 feet long, is a food fish of some importance in the south Pacific, Japan, Hawaii, and the Gulf of California. Foreign names for it are chani, awa, auge, sabalo, etc.

MILKING MACHINE. An apparatus designed to do away with hand labor in milking cows. Milking tubes, inserted into the milk ducts within the teats, have been tried, but

found unsatisfactory. Several forms of milking machines have been devised which milk a number of cows at the same time. The most successful of these operate on the principle of a vacuum maintained by a hand or power air pump and so arranged as to give a pulsating action. Pipes connected with the apparatus pass to the stalls and terminate in closed cans fitted with hose and cups, which fit over the cows' teats so as to make an air-tight joint. A pulsating action resembling hand milking or the sucking of the calf is imparted by the vacuum apparatus, alternating in pressure from five to fifteen pounds at quite rapid intervals. In recent years the milking machine has been developed to a quite high state of perfection. Several forms are rapid and effective, but are expensive to install and maintain, and must be thoroughly cleaned or they will soon become foul and contaminate the milk. As yet milking machines have come into only limited use either in America or Europe.

MILK LEG. See PHEGMASIA ALBA DOLENS.

MILKOWSKI, mil-kóf'ské, ZYGMUNT (1824-1915). A Polish novelist, who wrote under the pseudonym Theodor Thomas Jez. He was born at Saracea in Podolia, and was educated at the Odessa Lyceum and at the University of Kiev, where he made a special study of physics and mathematics. He took an active part in the Hungarian uprising of 1848 and then traveled in the East. After identifying himself with the Polish insurrection of 1863 he was obliged to live abroad. He lived in Zurich and was curator of the Polish museums at Rapperswil. Besides romances founded upon Slavic history he wrote stories of contemporary life in which the manners and customs of the south Slavonians and Hungarians are faithfully portrayed. Among the best of these are *Handzia Zahornicka* (1860); *Szandor Kovacz* (1861); *Historja o prapraucnuku i prapradziatku* (1864); *Uskoki* (1870). Among his later works are *Ofiary* (1874); *Hercóg Slowianski* (1876); *Narzewozna Harambaszy* (1882); *Rycerz chrzescianski* (1890). Less successful than these were his Polish historical novels, such as *Derstarb z Rytician* (1872); *Za Króla Olbrachta* (1876); *Z ciezkich dni* (1881).

MILK POWDER. See MILK.

MILK PRODUCTION. In a well-conducted dairy farm the following conditions should be enforced: the stable or cow house should be roomy, clean, dry, light, and well ventilated, for only under such conditions can cows be kept in the best of health. The animals themselves should be clean and healthy and should be well fed and contented. There should be an abundance of pure water, to which the cows should have access at least twice a day. The food should be of good quality and the grain and coarse fodder should be free from dirt and decay and not in a musty condition. All utensils which come in contact with milk should be thoroughly washed and sterilized or scalded after using. After the milk has been drawn from the cow it should be taken to a milk room which is free from all stable and other odors, poured through a fine strainer, and run over a cooling aerator (q.v.), to free it of animal and stable odors and cool it quickly. The milk is next transferred to the shipping can and set in cold water, or bottled and stored in a cold place until needed. During transportation from the farm to the town or city the milk should be kept

as cool as possible. Refrigerator cars are provided by some railroads for that purpose. Much of the milk that is brought to large cities by rail is from 24 to 36 hours old before it reaches the consumer. This makes it necessary to exercise every precaution in its handling, in order to prevent spoiling, and cooling immediately after milking is an important factor in this connection.

Not only has the demand for clean, pure milk increased greatly, but it has led to the enactment of more rigid restrictions and closer supervision of dairies and to the production at some dairies of so-called sanitary milk. Such milk is produced under the most sanitary and hygienic conditions as regards the food and care of the animals, the stables, the milking, and the care and handling of the milk. The herds in these dairies are inspected often to determine their freedom from disease, and not infrequently the milk is "certified" or guaranteed to contain a certain fixed percentage of fat, as 5 per cent, this being maintained the year round by the addition of cream when necessary. Such sanitary or certified milk is usually sold at an advanced price, as the cost of its production is greater than that of ordinary market milk. The so-called modified milk is a prepared product used principally for infant feeding, and usually made according to a physician's prescription. Some physicians prescribe a milk with a definite composition, usually resembling mother's milk as closely as possible, but varying according to the apparent needs of the individual. Such prescription milk is generally prepared from cows' milk by reducing the amount of fat, and more particularly that of proteids, and increasing the proportion of sugar. Lime water is frequently added to reduce the acidity, and at times preparations made from cereals are added.

For the preservation of milk pasteurization is now extensively practiced. Pasteurization consists in heating the milk in closed vessels at from 60° to 65° C. (140° to 150° F.) for about half an hour and then cooling it as quickly as possible by cold water or ice. By this means most of the organisms contained in it are killed, and the milk will keep much longer than when it has not been so treated. Continuous pasteurizers are used in many creameries and large dairies, and there are a variety of small pasteurizers for family use. Where there is any doubt as to the purity of the milk it is much safer to pasteurize that used for children at home. To a certain extent, however, pasteurization may be used to cover up the effects of careless methods, and many people prefer the sanitary milk. In sterilizing milk the liquid is heated to boiling: but this changes the character of the milk, making it less suitable for drinking and giving it a cooked taste. Pasteurization is sufficient for household purposes.

Statistics. According to the returns of the census of 1910, over 20,000,000 cows are kept in the United States for the production of milk. These produce annually nearly 6,000,000,000 gallons of milk. The total value of the milk consumed as such was estimated at \$252,436,757, and of the cream, \$37,655,047. The total value of the milk, cream, and butter fat sold and the butter and cheese made in the United States in 1909 was \$596,413,463.

See also BUTTER; BUTTERMILK; CHEESE; CREAMERY; DAIRYING; WHEY.

MILK SNAKE, or HOUSE SNAKE. A com-

mon widely spread North American colubrine snake, classified as an Eastern variety (*triangulus*) of the Southern king snake (*Osecoia*, or *Ophibolus doloiatus*). It sometimes reaches a length of 4 feet, and its general color above is yellowish gray, with a dorsal series of large blotches, normally 55 in number, and separated by narrow intervals, which are dull chocolate bordered with black. There is also a double row of rounded spots along the sides and a dark band from the eye back to the corner of the mouth. The abdomen is yellowish white, with square black blotches alternating with those above them. This subspecies is abundant in the Middle States and southern Ontario, changing

MILK SNAKE.

southward and west of the Mississippi into other forms of this far-extended and highly variable species. (See KING SNAKE.) Everywhere it is an entirely harmless denizen of fields and gardens, and often comes into barns and outhouses in search of the mice upon which it principally feeds, thereby deserving the protection of farmers. It is swift and agile. Its name milk snake comes from the frequency with which it is seen in dairies or places where milk is kept. It is believed to drink the milk, and there seems to be good evidence that it does so. Another popular belief is that this snake sometimes sucks the milk from the teats of cows, and this belief seems to be founded upon fact, although the occurrence is much less common than some persons believe. See Plate of SNAKES, AMERICAN HARMLESS.

MILK SUGAR. See SUGARS.

MILK TEST. See MILK; DAIRYING.

MILKWEED. See ASCLEPIAS.

MILKWEED BUTTERFLY. A cosmopolitan butterfly (*Anosia pleasippus*) which is found in nearly all parts of the world where milkweeds (*Asclepias*) grow. It is also known as monarch butterfly. It is a large reddish species, with its wing veins blackened, and its larva is striking in color, being grayish white and yellowish, transversely banded with black, giving it a zebra-like appearance. The chrysalis is delicate pale green with bright golden spots, and hangs from the leaves or stems of the food plant. The milkweed butterfly is a famous species for several reasons. It is one of the strongest flyers known among the Lepidoptera; specimens have been taken on vessels many hundreds of miles from the land, and there is in the United States an annual migration northward in the spring from the States bordering on the Gulf of Mexico. (See MIGRATION OF ANIMALS.) These flights, aided by the south winds, may reach up into Canada, the butterflies occasionally alighting and laying their eggs upon the milkweeds. In the autumn there is a return migration south, and the butterflies hibernate only in the Southern States, hidden away beneath the bark of trees and in other protected places.

Ordinarily the butterflies frequent open ground, but when they congregate, as at night and in cloudy weather, they are found resting on the stems of herbaceous plants, usually in the open spaces of forests, and in enormous num-

bers. They will alight upon the lee side of a tree, and particularly on the lower branches, in such vast numbers as almost to hide the foliage and to give their color to the trees. If disturbed, they rise like a flock of birds, but immediately settle again. Sometimes a tree will be so festooned with butterflies that it appears, at a short distance, to be covered with dead leaves.

This butterfly is one of the especially protected species, and is provided with scent scales, "androconia," which are supposed to make the insect distasteful to its natural enemies. It is the commonest and most widespread representative of the large group of butterflies which are thus protected, and is mimicked in coloration by other nonprotected species, e.g., in the United States by *Basilarchia disippus*, or *archippus*. Consult S. H. Scudder, *The Life of the Butterfly* (New York, 1893). See BUTTERFLIES AND MOTHS; MIMICRY; VICEROY.

MILKWORT. A plant common in the north temperate zone. See POLYGOALA.

MILKY WAY. See GALAXY.

MILL (AS. *mylon*, *myln*, from Lat. *molina*, mill, from *mola*, millstone, from *molere*, to grind; connected with Eng. *meal*, mold). A name originally given to machinery for grinding grain for food or to the factory where this was done. The term is now applied in a general way to many other kinds of manufactories besides those where raw material is transformed by a grinding process, as a saw mill, planing mill, or cotton mill. It is also applied in a special sense to a steel rotating cutter for shaping raw material or metal stock. See FLOUR; ROLLING MILL; GRINDING, CRUSHING, AND PULVERIZING MACHINERY.

MILL, HUGH ROBERT (1861-). A Scottish geographer, born at Thurso (Caithness) and educated at Edinburgh University, where he received the degree of D.Sc. in 1886. He served as chemist and physicist to the Scottish Marine Station (1884-87), was a university-extension lecturer (1887-1900), and after 1900 edited *British Rainfall* and *Symons's Meteorological Magazine*. In 1901 he was president of Section E of the British Association and in 1907-08 president of the Royal Meteorological Society. He became chairman of the trustees and director of the British Rainfall Organization. His writings include: *Realm of Nature* (1892; new ed., 1913); *The Clyde Sea Area; the English Lakes* (1895); *Hints on the Choice of Geographical Books* (1897); *New Lands* (1900); *The Siege of the South Pole* (1905); besides many articles. He became best known perhaps as the editor of *The International Geography* (new ed., 1911).

MILL, JAMES (1773-1836). A British economist and philosopher. He was the son of a shoemaker, and was born near Montrose, Scotland, April 6, 1773. He studied at the University of Edinburgh, where he distinguished himself in Greek and in moral and metaphysical philosophy. He was licensed to preach in 1798, but instead of following this career he went to London in 1802 as tutor to Sir John Stuart's children and there settled as a literary man. He became editor of the *Literary Journal* and of the *St James's Chronicle* and wrote for various periodicals. Not long after he was established in London he made the acquaintance of Jeremy Bentham, who influenced him greatly in his views. In 1806 he commenced his *History of British India*, which he carried on along with

other literary work and published in the winter of 1817-18. This important work, though containing an attack upon the administration of the East India Company, secured for him in 1819 the post of assistant examiner of Indian correspondence. Before his death he was appointed head of the examiner's office, where he had the control of all the departments of Indian administration—political, judicial, and financial—managed by the secret committee of the court of directors. He contributed many important articles to the *Encyclopædia Britannica* (1814). Some of these essays were printed in a separate form and became widely known. In 1821-22 he published his *Elements of Political Economy*, a work prepared primarily with a view to the education of his eldest son, John Stuart Mill. In 1829 his magnum opus, the *Analysis of the Human Mind*, appeared. The work is almost the Bible of associationism and deserves to be classed among the great English philosophical productions. He attempted to simplify associationism by recognizing only one principle at work—that which was later called association by contiguity. (See ASSOCIATION OF IDEAS.) This principle can so fuse various ideas and feelings that a result may be produced entirely different from the original element. This has been called mental chemistry. In his *Fragment on Mackintosh* (1835) Mill made great use of mental chemistry in support of the doctrine that morality is based on utility. (See UTILITARIANISM.) In this way he furnished a psychological basis for Bentham's ethical and legislative reforms. He took great interest in political questions and was a powerful advocate of an extended suffrage. Much of his influence was due to his strong personality and great conversational powers. In later life he entirely broke away from his early religious views and brought up his son John Stuart in utter religious indifference. He took a leading part in the founding of University College, London. He died at Kensington, June 23, 1836. Consult: J. S. Mill, *Autobiography* (London, 1873; new ed., ib., 1908); Alexander Bain, *James Mill: A Biography* (ib., 1882); Sir Leslie Stephen, *The English Utilitarians*, vol. ii (New York, 1900).

MILL, JOHN (1645-1707). A scholar of the Church of England. He was born at Shap, Westmoreland, studied at Queen's College, Oxford, and was elected a fellow in 1670. He entered the ministry and became distinguished as a preacher; he became rector in 1681 of the college living of Bletchington, Oxfordshire, and chaplain to Charles II. In 1685 he was principal of St. Edmund Hall and in 1704 became prebendary of Canterbury. The work for which he is most distinguished is his new edition of the Greek Testament, on which he spent 30 years and which appeared only 14 days before his death. It was undertaken at the advice and expense of Dr. Fell, Bishop of Oxford, but after the Bishop's death (1686) Mill continued it at his own expense and repaid to the executors what he had received. The text which Mill adopted is that of Robert Stephens of 1550, and his work contains 30,000 various readings collected from manuscripts, commentaries, writings of the fathers, etc. Dr. Daniel Whitby attacked the work in his *Examen Variantium Lectionum Johannis Millii* (London, 1709); but Dr. Richard Bentley approved the labors of Mill, and Michaelis, Marsh, and other critical scholars acknowledged the value of the edition.

MILL, JOHN STUART (1806-73). An English philosopher, the son of James Mill. He was born in London, May 20, 1806, and was educated at home by his father, who gave his precocious son an extraordinary amount of learning at a very early age. He is said to have begun Greek at three. He was never allowed to indulge in the plays of childhood. In 1820 he went to France, where he lived for upward of a year, making himself master of the French language and occasionally attending public lectures on science, but also, now that he was away from his father, getting some physical exercise in fencing and like sports. This stay in France gave him an intense appreciation for the pleasures of travel, and to the end of his days he was an ardent lover of mountain scenery. But the world of men had also its interest for him while he was abroad, for then he laid the foundation of his great familiarity with and interest in the politics as well as the literature of the French nation. On his return he read law, history, and philosophy, and in 1823 entered the India House as a clerk in the examiner's office, where his father was assistant examiner. For 33 years he was in the service of this company, gradually rising till at last he was head of his department, as his father had been before him. When the government of India was transferred to the crown in 1858, he declined a seat on the New Indian Council and retired from office in October of the same year, on a compensating allowance. At the general election of 1865 Mill was returned to Parliament for Westminster, and till he lost his seat at the election of 1868 he acted with the advanced Radicals and urged the extension of suffrage to women. In 1851 he married Mrs. John Taylor, who had been an intimate friend long before her first husband's death. He ascribed to her influence many of his most cherished ideals; she died in 1859, but Mill's devotion to her memory was his religion till his death, which took place May 8, 1873, at Avignon, where he had spent the greater part of the last years of his life.

Mill became an author at a very early age and may be looked upon as one of the foremost thinkers of his time. His first publications consisted of articles in the *Westminster Review*. He took an active part in the political discussions that followed the revolution of 1830 in France and the reform-bill movement in England; and from 1835 to 1840 was editor and, along with Sir W. Molesworth, proprietor, of the *London and Westminster Review*, where many articles of his own appeared. His chief works are: *A System of Logic, Ratiocinative and Inductive* (1843; 9th ed., 1875); *Principles of Political Economy* (1848; ed. by Ashley, 1909); *On Liberty* (1859); *Discussions and Dissertations* (4 vols., 1859-74); *Utilitarianism* (1863); *Comte and Positivism and the Examination of Sir William Hamilton's Philosophy* (1865); *Inaugural Address at the University of St. Andrews* (1867); *England and Ireland* (1868); *The Subjection of Women* (1869); *Chapters and Speeches on the Irish Land Question* (1870). He also edited with copious notes his father's *Analysis of the Phenomena of a Human Mind* (London, 1869). After his death appeared his *Autobiography* (1873) and *Three Essays on Religion* (1874). A collected edition of his works appeared in 1905-10. Two volumes of his *Letters* also appeared in 1910. In philosophy he was an empiricist, sensationalist, and asso-

ciationist. In ethics he was a utilitarian, but departed from the utilitarianism of Bentham by recognizing differences in quality as well as in quantity of pleasures. "It is quite compatible," he says, "with the principle of utility to recognize the fact that some kinds of pleasure are more desirable and more valuable than others. It is better to be a human being dissatisfied than a pig satisfied; better to be Socrates dissatisfied than a fool satisfied." Experience determines the rank of pleasures in the scale of quality; on this point he, perhaps unconsciously, follows Plato, assuming, contrary to fact, that experience gives the same valuation in all cases. In political theory Mill was a modified individualist, believing that every man should be allowed all liberty compatible with the liberty of his fellows. The tendency of modern thought has been so far away from individualistic standards that Mill's renown has been somewhat obscured, but his influence on his own generation would be difficult to overestimate. In metaphysics he followed the Humean tradition: the mind is "a series of feelings which is aware of itself as past and future," and matter is "the permanent possibility of sensations." His greatest work, however, was in logic, to which he added a fruitful treatment of the subject of induction (q.v.). His work in this science was considerably impaired by his sensationalistic empiricism, but when everything is taken into account, it must stand alongside that of Aristotle and of Hegel. His book was for many years the standard authority among those who shared his general standpoint in questions of philosophy, though it was keenly criticized from the opposite camp by Whewell and W. G. Ward.

Mill*, in *Green's Works*, vol. ii (ib., 1886); Theodor Gomperz, *J. S. Mill* (Vienna, 1889); W. L. Courtney, *Life of J. S. Mill* (London, 1889); Charles Douglas, *John Stuart Mill, a Study of his Philosophy* (ib., 1895); id., *The Ethics of John Stuart Mill* (ib., 1897); John Watson, *Comte, Mill, and Spencer* (New York, 1895; subsequently revised and renamed *An Outline of Philosophy*, Glasgow, 1898); Sir Leslie Stephen, *The English Utilitarians*, vol. iii (New York, 1900); Ernest Albee, *History of English Utilitarianism* (London, 1902); Thomas Whittaker, *Comte and Mill* (New York, 1909); John MacCunn, "The Utilitarian Optimism of John Stuart Mill," in *Six Radical Thinkers* (ib., 1910); S. P. Cadman, "John Stuart Mill," in *Charles Darwin and Other English Thinkers* (Boston, 1911); A. S. Pringle Pattison, *English Philosophers and Schools of Philosophy*, in "Channels of English Literature Series" (New York, 1912). Douglas's two works are especially to be commended to the reader who wishes to get in compact form a statement of Mill's doctrines in his own words. See POLITICAL ECONOMY.

MILLAIS, mil-lä', SIR JOHN EVERETT (1829-96). An English genre, landscape, and portrait painter. He was born at Southampton, June 8, 1829, and was brought up in the Isle of Jersey. In 1837 he received his first instruction in art from Bessel, a drawing teacher in Jersey. In 1838 and 1839 he studied at the School of Henry Saas in Bloomsbury, and the following years at the Royal Academy, in which he carried off

every prize, receiving a gold medal in 1847. In 1848 he became associated with William Holman Hunt, Dante Gabriel Rossetti, and others in the formation of the Pre-Raphaelite Brotherhood (q.v.). His work attracted the attention of Ruskin, for whom he made some architectural designs and whose portrait he painted. In 1855 he married Ruskin's divorced wife. He was made associate member of the Royal Academy in 1853 and member in 1863. From 1860 to 1870 he was employed as illustrator, and among other books illustrated Tennyson's poems and Trollope's novels. He was appointed Officer of the Legion of Honor at the Paris Exposition in 1878 and was an honorary member of the French Institute and of several foreign academies. He was created Baronet in 1885, and a few months before his death, which occurred in London, Aug. 13, 1896, he was made president of the Royal Academy.

Aside from his landscapes and portraits, his subjects include scriptural, historical, and legendary themes, scenes from everyday life, and a few national in character, such as "The Rescue" (1855), painted in honor of the London firemen. From 1847 to 1853 his work was strongly influenced by Pre-Raphaelite theories and aroused much criticism. Works of this period are: "Isabella" (1849, Liverpool Gallery); "Christ in the House of his Parents" (1850) and "Ophelia" (1852, both in the Tate Gallery); "The Proscribed Royalist" (1853); "The Huguenot" (1852). After 1855 his work developed greater individuality and breadth, but lost in intensity, and his composition became more commonplace. His landscapes betray the ardent nature lover; his portraits are painted with masterly characterization. His art is forceful and robust, and his color brilliant. From 1870 on he gave much of his time to portrait painting, his sitters including Gladstone (National Gallery) and Christ Church, Oxford; Leech, Lord Beaconsfield, Wilkie Collins, and Carlyle (all in the National Portrait Gallery); John Bright, Irving, Tennyson (Tate Gallery), and others. His landscapes include: "Spring" (1859); "Chill October" (1871); "The Vale of Rest" (1859, Tate Gallery); "Dew-Drenched Furze" (1881). Other important pictures are: "Eve of St. Agnes" (1863, water color, South Kensington Museum); "Effie Deans"; "The Black Brunawicker" (1860); "The Bride of Lammermoor" (1878) and "Portia" (both in the Metropolitan Museum, New York); "The Blind Girl" (1856, Birmingham Gallery); "The Northwest Passage" (1874); "The Order of Release" (1853); "The Boyhood of Raleigh" (1879); "A Yeoman of the Guard" (1877); "St. Stephen" (1895); "Speak! Speak!" (1895), and "A Disciple" (1895, all in the Tate Gallery).

Bibliography. Spielmann, *Millais and his Works* (London, 1898); J. G. Millais, *Millais' Life and Letters* (ib., 1899); A. L. Baldry, *Millais: His Art and Influence* (ib., 1899); Baslin, *Five Great Painters of the Victorian Era* (ib., 1902); *Masters in Art*, vol. ix (Boston, 1906); T. L. Hare, in *Leaders of English Pre-Raphaelites* (New York, 1909); J. E. Reid, *Sir J. E. Millais* (ib., 1909).

MILLAIS, JOHN GAILLE (1865-). An English artist and naturalist, born in London, a son of Sir John Everett Millais. He was educated at Marlborough and at Trinity College, Cambridge, and from 1886 to 1892, when he retired as first lieutenant, served in the

Seventy-second Highlanders. He shot big game in all parts of the world and made a remarkably large collection of British birds. Besides illustrating books on shooting and natural history, especially the *Encyclopædia of Sport*, to which he contributed, he wrote: *Game Birds and Shooting Sketches* (1892); *A Breath from the Veldt* (1895); *British Deer and their Horns* (1897); the *Life and Letters* (1890) of his father; *The Wild Fowler in Scotland* (1901); *British Surface-Feeding Ducks* (1902); *The Mammals of Great Britain and Ireland* (3 vols., 1904-06); *Newfoundland and its Untrodden Ways* (1907); an elaborate and beautifully illustrated *Natural History of British Game Birds* (1909); *British Diving Ducks* (1913); *Deer and Deer Stalking* (1913).

MILLAR, ANDREW (1707-68). A London publisher and bookseller, of whom Dr. Johnson said: "I respect Millar, sir; he has raised the price of literature." It was he who, with other aid, financed Johnson's *Dictionary* and saw it through the press. Among his notable publications were Thompson's *Seasons*, Fielding's *Tom Jones* and *Amelia*, and the histories of Robertson and Hume. Consult Charles Knight, *Shadows of the Old Booksellers* (London, 1865).

MILLARD, EVELYN (1873-). An English actress, born in London, the daughter of a professor of elocution. She made her début at the Haymarket in 1891 and in the same year played in Sarah Thorne's stock company and in repertoire with Fred Thorne's company. Then she was at the Adelphi (through 1893); played Paula in *Mrs. Tanqueray*; with Comyns Carr as Rosamund in *Sowing the Wind* (1895); at the St. James's (1894-96), playing Cecily Cardew in Wilde's *The Importance of Being Earnest* and Princess Flavia in *The Prisoner of Zenda*; and at Her Majesty's (1896) she created the rôle of Mademoiselle de Belle Isle in 1897. She was Portia in Beerbohm Tree's production of *Julius Caesar* (1898); Glory Quayle in Hall Caine's *Christian* (1899); Francesca in Stephen Philip's *Paolo and Francesca* (1902); the Countess de Roquelaure in Doyle's *Brigadier Gerard* at the Lyric (1906); and Joanna Rushworth in *The Beloved Vagabond* at His Majesty's (1908). In 1908 she managed the Garrick. She married Robert Porter Coulter in 1900.

MILLAU, mē'yô, or **MILHAU**. A town in the Department of Aveyron, France, on the Tarn, 74 miles north of Béziers (Map: France, S., G 4). Its chief building is the Romanesque church of Notre Dame, with a sixteenth century tower. There is a large botanical garden and parks. The town is the centre of a cattle-raising and grape-growing section and has a variety of manufactures, particularly of kid gloves, woolen goods, and dyed goods. There are oil wells near by. Millau was the Roman *Æmilianum Castrum*; during the religious wars it was a stronghold of Calvinism, and Louis XIII destroyed its ancient castle and walls in 1629. Pop. (commune), 1901, 18,701; 1911, 17,673.

MILLBANK PRISON. A famous London penitentiary in Westminster, facing the Thames. It was built in 1812 (finished in 1821) in accordance with the plans of Howard and Bentham. It could shelter 1100 inmates and was so constructed that from a central room every cell could be seen. The confinement was solitary. Those sentenced to penal servitude served a term here first. The prison was closed in 1890 and the buildings torn down in 1891. Consult G. P.

Holford, *Account of the General Penitentiary at Millbank* (London, 1828), and A. Griffiths, *Memorials of Millbank* (2d ed., ib., 1894).

MILL-BOY OF THE SLASHES. A popular nickname of Henry Clay, from a tract of swampy land called the Slashes near his birthplace in Hanover Co., Va.

MILLBURY. A town in Worcester Co., Mass., 6 miles southeast of Worcester, on the Blackstone River and on the New York, New Haven, and Hartford and the Boston and Albany railroads (Map: Massachusetts, D 4). It has a public library and is extensively engaged in the manufacture of cotton and woolen goods, edge tools, foundry and machine-shop products, loom harness and heddles, linen cloth and thread, and felt goods. From 1743 to 1813, when it was incorporated, Millbury was the north parish of Sutton. The lyceum lecture system is said to have originated here about 1820. Pop., 1900, 4460; 1910, 4740.

MILLE, mël, PIERRE (1864-). A French journalist and author, born at Choisy-le-Roi and educated at the Collège Rollin. He was sent to Madagascar on several missions; was war correspondent for the *Journal des Débats* during the Græco-Turkish War in 1897; and traveled widely. He was created a Knight of the Legion of Honor. Among his writings are: *De Thessalie en Crète* (1898); *Au Congo belge* (1899); *Sur la vaste terre* (1906); *La biche écrasée* (1910); *Caillou et Pili* (1911); *Louise et Barnavaux* (1912).

MILLEDGE, JOHN (1757-1818). An American soldier and statesman, born in Savannah, Ga. When the Revolution began he was one of the party which seized Wright, the royal Governor of the Colony. Milledge escaped from Savannah when it was taken by the British in 1778, and he assisted in the unsuccessful siege of the town by the Americans in 1779. In the following year he was made Attorney-General of Georgia. After the war he was several times elected a member of the State Legislature, and was a Representative in Congress from 1792 to 1798 and again from 1801 to 1802, when he resigned to become Governor. In 1802 he was one of the three commissioners who negotiated the cession of Georgia's western territory to the United States. From 1806 to 1809 he was a United States Senator. Milledge took an active part in establishing the University of Georgia, and gave the institution 700 acres of land, upon which the university and a part of Athens now stand. The town of Milledgeville was named in his honor.

MILLEDGEVILLE. A city and the county seat of Baldwin Co., Ga., 32 miles northeast of Macon, on the Oconee River, at the head of navigation, and on the Georgia and the Central of Georgia railroads (Map: Georgia, C 2). It is the seat of the Georgia Military College and the Georgia Normal and Industrial College for Girls and of the Georgia State Sanitarium for the Insane, which accommodates 4000 patients. The prison farm, 3 miles northwest of the city, employs some 400 State convicts. The city is the centre of a cotton-growing region and its industrial interests are mainly in the preparation of this staple for market, and in the manufacture of brick, tile, cement, and sewer pipe. The government, under a charter of 1900, is administered by a mayor, elected every two years, and a unicameral council, of which the mayor is a member, chosen on a general ticket. Mil-

ledgeville, named in honor of Gov. John Milledge of Georgia, was laid out in 1803, was chartered as a city in 1836, and was the capital of the State from 1807 to 1867, the government buildings now being utilized by the colleges. Pop., 1900, 4219; 1910, 4385.

MILLENARIANS. See MILLENNIUM.

MILLENARY (Lat. *millenarius*, containing a thousand, from *milleni*, a thousand each, from *mille*, thousand). A period of a thousand years, specifically the celebration of the one-thousandth anniversary of an event. The most important millenary was that commemorating the death of Alfred the Great, which was held in Winchester, England, Sept. 18-21, 1901, which culminated in the unveiling of a large bronze statue of King Alfred by Hamo Thornycroft.

MILLENARY PETITION. A petition presented by Puritan clergy to King James I in April, 1603, when on his way to London to take his throne. It is so called because it was intended to have 1000 signatures, although as a matter of fact it had only 750. The original of the petition is supposed to be lost, but Fuller gives it in his *Church History* (Book x, 27, ed., London, 1837, vol. iii), and it is thence reprinted by Gee and Hardy, *Documents Illustrative of English Church History* (London, 1896; pp. 508-511). It sets forth in firm but respectful language those points connected with the Church service (cross in baptism, baptism by women, public reading of the Apocrypha, unabridged liturgy, etc.), the Church ministry (illiterate ministers, nonresidency, clerical celibacy), the Church revenue (commendams, pluralities, impropriations), and with the Church discipline (excommunications for trifling causes, extortionate fees, protracted ecclesiastical suits, frequency of marriages without banns asked), which the Puritan party would see removed or modified. The King's answer was the calling of the Hampton Court Conference in January, 1604, which resulted in no redress, but rather the confirmation of the abuses complained of, but which led to the preparation of the Authorized Version of the Bible.

MILLENNIUM (Neo-Lat., from Lat. *mille*, thousand + *annus*, year). A period of 1000 years preceding the final judgment (q.v.), during which, according to a widely accepted system of Christian eschatology, the Christ and his saints will reign on the earth. The division of the world's course into periods is found among many peoples. Thus, the Hindus divided the history of the world into *kalpas* of hundreds or thousands of years, and the Incas made four great periods. (See ESCHATOLOGY.) A long national existence and a tradition of certain epoch-making events naturally account for such a partition. The Persians counted 12 periods each of 1000 years. It is likely that this division into 12 parts was derived from the Babylonians, and ultimately goes back to calculations of the sun's course through the 12 signs of the zodiac. It is significant that the third, fourth, fifth, sixth, seventh, and eighth thousand years are attributed respectively to Cancer, Leo, Virgo, Libra, Scorpio, and Sagittarius in *Bundahish* 34. The number 1000 may have a different origin, since the great cosmic year would demand a larger figure. According to the Parsi doctrine, 6000 of the 12,000 years are occupied by the history of man. Zarathustra appears at the beginning of the fourth and the Saoshyant will come at the end of the last to raise the dead and

to renew the world. While this doctrine is fully presented only in late Pahlavi writings, such as the *Bundahish* and the *Dinkart*, there are indications of a much higher age, as Mani (c.200 A.D.) was familiar with the Zoroastrian doctrine of a cycle of 12,000 years, and Berossus (c.300 B.C.) seems to have rationalized the doctrine of *Zrvan akarana*, boundless time, and its period. It is altogether probable that the conception that human history would endure 6000 years before the Messianic age came into Jewish thought from a Persian source. The scriptural justification was found in Ps. xc. 4, "A thousand years in thy sight are but as yesterday when it is past," and the length of the Messianic age was inferred from an interpretation of Gen. ii. 2, based on the word of the Psalmist, as is seen by utterances of rabbis living in the second century A.D. (*Midrash Tehillim* to Ps. xc and *Yalkut Shimeoni* to Ps. lxxii.) Before the fall of Jerusalem in 70 A.D. there is no evidence that the expected Jewish world empire, whether with or without a Messiah, was thought of as being of limited duration. That Israel would never yield its supremacy to any other nation was a firm conviction. The Messianic King was probably looked upon as the founder of a dynasty. Towards the end of the first century, however, the conception of the Messiah became more transcendent, and his reign might be thought to last "until the corruption of the world should end," characterized by great prosperity (*Apocalypse of Baruch*, xl. 3, xxix, lxxiii), or, more precisely, 400 years to be followed by seven days of silence, the general resurrection, and the last judgment (q.v.) as set forth in the *Apocalypse of Ezra* (vii. 28, 29). The first mention of the millennium is in the *Slavonic Enoch* (xxxii. 2-xxxiii. 2); but in this book there is no Messiah. A summary of opinions in the Babylonian Talmud (*Sanhedrin* 97a, 99a) shows that it was comparatively seldom that a Jewish teacher estimated at 1000 years the length of Yahwe's reign, 40, 70, 365, 400, 600, 2000, and 7000 years being suggested by different teachers.

In the New Testament the doctrine of a millennium is clearly taught in Rev. xx. After the returned Messiah has conquered the beast, Satan is cast into the abyss in chains for 1000 years, the martyrs are raised from the dead and reign with Christ as kings and priests during the millennium. At the end of the millennium the powers of evil are let loose again for a short time, whereupon follow the resurrection of the rest of the dead, the last judgment, the destruction of death and Hades, which is the second death, and the new heavens and the new earth. Critical exegesis agrees with the Chiliasts of the early Church and the present premillenarians that the author of this passage no doubt believed that Jesus would return upon the clouds before the millennium to reign with some of his saints for 1000 years in visible form. It cannot be proven, however, that other writers in the New Testament cherished this view, or that they all held the same opinion concerning the world's future. The Gnostics rejected this doctrine and their opposition was continued by such teachers of the Alexandrian school as Clement and Origen. On the other hand, Irenæus informs us (*Adv. Haer.*, v, 33) that Papias, Bishop of Hierapolis, had recorded as a saying of Jesus a remarkable description of the fertility of the vine in the millennium: the epistle attributed to Barnabas describes the millennium as a period of

rest following 6000 years of work to be ushered in by the return of Christ (xv, 5); and Justin Martyr likewise expressed his belief in the pre-millennial coming of Christ and the thousand years of his reign in Jerusalem (*Apol.* 52; *c. Tryph.* 45, 49, 113). Irenæus, Tertullian, and Hippolytus were also Chiliasts. An ardent expectation of the millennial kingdom characterized the Montanists, who looked for its establishment at Pepuza in Phrygia. The reaction against Montanism led to a more general rejection of the doctrine of a millennium. Dionysius of Alexandria attacked the very foundation of this doctrine in denying the Johannine authorship of Revelation. Such doubts did not disturb the Western Church, and men like Commodian and Lactantius were Chiliasts. Only through the influence of Jerome and especially Augustine, whose *Civitas Dei* identified the Church with the kingdom of God and the millennium with the history of the Church, did Latin Christianity commit itself to an eschatological programme excluding the premillennial advent, the first resurrection, and the visible reign on earth. During the Middle Ages earnest and spiritually minded men, grieved at the many abuses that spread in the Church, could not but look for divine chastisement. While there does not seem to be sufficient foundation for the current statement that the end of the world was generally expected about the year 1000 A.D., there are many indications of the anxiety that at sundry times filled pious hearts as well as guilty consciences. The great hymn *Dies iræ, dies illa* reveals both a fearful looking forward to the impending judgment and the part that the Sibylline Oracles and similar works played in creating this mood. Millenarian views were held by men like Joachim of Floris and Occam and by numerous religious bodies. In the Reformation era the hope of a speedy establishment of the Messianic kingdom was especially cherished by many of the Baptists. They were led to it by their doctrine of the inner light and the continuance of prophecy, by their sympathy with the oppressed, and by their disapproval of the union of church and state. Looking to God alone for the establishment of the truth and the righting of social wrongs, and expecting a direct revelation from Him, some naturally were led astray by their impulses under pressure of circumstances. But the establishment of the millennial kingdom by John of Leyden (q.v.) at Münster was an error regretted and condemned by the great majority of Baptists. The Fifth Monarchy men of Cromwell's time looked upon the millennium as having actually begun with the overthrow of the royal family in England. Many English mystics looked forward to the second advent in the year 1666, and their faith found a curious reflection even in Judaism. (See MESSIAH.) Chiliastic views were embraced by Comenius, who translated into Latin a number of recent prophecies as to the end of the world, Jurieu, Spener, and other pietists. Swedenborg held that the millennial dispensation began in 1757. Bengel calculated that the millennium would commence in 1836; Miller expected it in 1843; Channing in 1867; Baxter in 1881. While some premillenarians devote much attention to prophetic chronology, assuming a double fulfillment of the predictions in Daniel and Revelation, others refrain from all attempts at fixing the date, but are obliged by the natural interpretation of Rev. xx, with their view of biblical infallibility,

to affirm the visible coming of Christ before the millennium. Among the latter are many learned theologians of recent times. The opinion that this visible coming of Christ will occur after a long period of universal prevalence of Christianity supposed to be vaguely indicated by the thousand years is more widely accepted, but it is further removed from the conceptions of early Christianity and cannot readily find the scriptural support that it demands. The distinction between premillennialism and postmillennialism is rapidly losing its significance, as modern theology has a tendency to look upon the primitive Christian expectation of the return of Jesus as an illusion, historically necessary, but not of permanent worth; to consider the absolute victory of one system of religious faith and practice less desirable than the ascendancy of what is morally most excellent in all creeds and cults; and to expect a gradual improvement of the social conditions and the character of the human race to be wrought by actually operating forces.

MILLEPORE (from Lat. *mille*, thousand + *porus*, passage, pore). A coral-forming hydroid, of the order Hydrocorallina, so named from the numerous minute pores or calices dotting its surface, which are arranged in irregular circular groups. As the single animal is microscopic, and as it grows in compound coral-like masses on reefs in tropical seas, it was at first confounded with the corals, but was eliminated from the corals first by L. Agassiz and afterward by Moseley. The animal is not a coral polyp, being allied rather to *Hydra*, and especially to *Hydractinia* and *Clava*, common on northern coasts. The coral stocks form irregular branching masses, several inches high and sometimes a

foot or more broad. The mass of the coral incrustation consists of fibres (canals or tubes) traversed in all directions by tortuous spaces forming regular branching systems, like a tree, in which *Millepora* differs from the coral stocks (coralla). The animals are of two kinds. Those inhabiting the central cup or pore are short thick zooids. (See POLYMORPHISM.) These are the "feelers"—they take in the food. The zooids in the smaller, outer pores of the circle are the reproductive zooids. That *Millepora* is a true hydroid is proved by the coral stock being at the base provided with canals by which the several zooids are kept in union with one another by the form of the zooids themselves, by the absence of all trace of mesenteries (which characterize coral polyps), and by the presence

MILLEPORA.

Animal of *Millepora nodosa*. a, nutritive zooid; b, reproductive zooid; c, lasso cell; d, the same coiled up in its cell; e, a third form. (All highly magnified.)

of thread cells (see NEMATOCYST) of the form peculiar to hydroids. Finally, the position of *Millepora* as a hydroid has been satisfactorily settled by the discovery, by Duerden in 1899, in Jamaica, of free-swimming female medusæ. (See HYDROZOA.) The Floridian and West Indian species is *Millepora alcornia*. Consult articles by L. Agassiz, Moseley, Duerden, in *Nature* (London, 1899-1900). See Plate of CORAL.

MILLER, ADOLPH CASPAR (1866-). An American economist, born in San Francisco. He graduated from the University of California in 1887 and from Harvard (A.M.) in 1888 and studied at Paris and Munich in 1895-96. He was instructor in economics at Harvard in 1889-90, assistant professor of history and politics at the University of California in 1890-91, associate professor of political economy and finance at Cornell in 1891-92, professor of finance at Chicago from 1892 to 1902, and Flood professor of economics and commerce at the University of California in 1902-13. In the latter year he became assistant to the Secretary of the Interior at Washington and in 1914 he was appointed by President Wilson a member of the newly created Federal Reserve Board. He published *The Monetary Problem in the United States* (1895).

MILLER, CHARLES (1843-). An American capitalist and philanthropist, born at Oberhoffen, Alsace. He came to the United States in 1854; entered the oil business in 1869; and became president of the Galena-Signal Oil Company and director of the American Locomotive Company, the American Steel Foundry Com-

pany, the Railway Steel Spring Company, and about 40 other corporations. He served as mayor of Franklin, Pa., for two terms, as member of the Pennsylvania State Board of Charities for six years, and as major general in the Pennsylvania National Guard in 1900-06. He maintained a night school at Franklin, and was made a Chevalier of the French Legion of Honor.

MILLER, CHARLES HENRY (1842-1922). An American landscape painter, born in New York City. He first studied to be a physician, but gave up this profession for art. After studying in Vienna and Berlin he went to Munich in 1867 and became a pupil of Lier and of the Bavarian Academy. Afterward he settled in New York, where he became an Academician in 1875 and one of the first members of the Society of American Artists. He belongs to the older school of American painters. His best canvases include "Sunset, East Hampton" (1878, Brooklyn Museum); "Bouquet of Oaks" (Metropolitan Museum, New York); "High Bridge" (Democratic Club, New York). He wrote *The Philosophy of Art in America* (1885) under the pen name of Carl de Muldor.

MILLER, CHARLES RANSOM (1849-1922). An American newspaper editor. He was born at Hanover, N. H., and graduated from Dartmouth College in 1872. He served on the staff of the *Springfield Republican* in 1872-75, and then joined the staff of the *New York Times*, becoming an editorial writer in 1881 and editor in chief in 1883. He also became vice president and director of the *New York Times Company*. In 1913 he was special lecturer at the Columbia School of Journalism. He received the honorary degree of LL.D. from Dartmouth in 1905, and that of Litt.D. from Columbia in 1915. His brilliant leader of Dec. 15, 1914, "For the German People, Peace with Freedom," demanding the overthrow of German militarism, was widely commented on at home and abroad, and, in general, the editorial page of the *Times* was maintained under his direction at a high level of excellence during a long period.

MILLER, CINCINNATUS HEINE, better known as JOAQUIN MILLER (1841-1913). An American author, born in Wabash District of Indiana, Nov. 10, 1841. In 1854 his parents took him to Oregon. Later he became a gold miner in California. He was a volunteer in Walker's Nicaragua expedition of 1855. From 1855 until 1860 he lived among the Indians of the Pacific coast. He studied law for a while, then edited at Eugene, Oreg., a Democratic paper, which was suppressed by the authorities for disunion sentiments. In 1863 he began to practice law and in 1870 he was appointed county judge of Grant Co., Oreg. After visiting the Eastern States Miller went to England, where (and also in Boston) in 1871 he published his *Songs of the Sierras*, which made him a "lion" in London society. In London he lived up to the British conception of the American Western type by appearing on festal occasions and in general in flannel shirt, sombrero, etc. He afterward settled in New York, but left that city in order to do journalistic work in Washington, D. C., and in Oakland, Cal. At his Oakland home, which was a feature of the city, he entertained many visiting celebrities. He died Feb. 17, 1913. In accordance with his wish his body was cremated and the ashes carried up into the Sierras and thrown to the winds. In addition to the *Songs of the Sierras* above mentioned, his

work includes: *Songs of the Sunlands* (1873); *Songs of Italy* (1878); *Songs of the Mexican Seas* (1887); *Building of the City Beautiful* (1893); in prose, *The Danites in the Sierras* (a novel, 1881). Miller's play, *The Danites*, taken from his novel, had considerable success, and his poetry received some favorable notice, more for genuinely romantic content and brilliant if crude color, than for artistic excellence. A collective edition of his verses appeared in 1897. The name Joaquin is supposed to have been taken from Joaquin Murieta, a Mexican bandit, of whom Miller wrote a defense. In the *Poems* (6 vols., San Francisco, 1909-10) will be found (in volume i) an introduction and an autobiography.

MILLER, EDWARD (1760-1812). An American physician, born in Dover, Del. He graduated from the medical department of the University of Pennsylvania in 1784 and in 1797, associated with Dr. Samuel L. Mitchell (q.v.) and Dr. Elihu H. Smith, he founded the *Medical Repository*, the first American journal of medicine. He was professor of the practice of medicine in the University of the City of New York in 1807-12. His report on "Yellow Fever in New York in 1805" remains a notable contribution to medical science. He enjoyed a high reputation both in the United States and abroad. Consult Samuel Miller, *Memoir and Writings of Edward Miller* (New York, 1814).

MILLER, FERDINAND, BARON VON (1842-). A German bronze founder and sculptor. He was born in Munich and studied under his father, Ferdinand von Miller (q.v.), and later with Hähnel in Dresden. For purposes of work and study he traveled extensively in France, Italy, and America. As lieutenant he served in the Franco-German War of 1870-71. In 1900 he was appointed director of the Bavarian Academy of Fine Arts and in 1912 he was made Baron. He cast upward of 70 colossal monuments, scattered throughout the world. His own work in sculpture includes statues of Humboldt, Shakespeare, and Columbus for St. Louis; figures for a large fountain at Cincinnati; the statue of a soldier for the Soldiers' Monument in Charleston; the equestrian statue of Emperor William I at Metz (1892); and, among many others in Bavaria, the army monument in the Feldheerenhalle at Munich and the equestrian statue of King Louis I at Regensburg (1902).

MILLER, FERDINAND VON (1813-87). A German bronze founder, born at Fürstfeldbruck. He studied at the Munich Academy and learned his trade under his uncle, Stiglmayer, and in Paris with Soyer. His reputation was won by his castings from the designs of Schwanthaler, and especially by his monumental works, including the colossal statue of "Bavaria" in Munich and of the "Germania" of the Niederwald monument. His best-known work in America, where he executed over 80 commissions, is the bronze door of the Capitol in Washington. His sons, Ferdinand (q.v.) and Ludwig (1850-1912), also became bronze founders and sculptors.

MILLER, FRANK AUGUSTUS (1859-). An American art collector and antiquarian, born in Tomah, Wis. He removed in 1872 to California and in 1879 founded at Riverside the Glenwood Mission Inn. This he subsequently enlarged from time to time, using always and with rare artistic taste distinctive architectural

features of the mission buildings erected in that region during the eighteenth and early nineteenth centuries by Franciscan padres. The resulting edifice has been considered the most consistent and beautiful example of mission architecture in existence. Here Miller gathered from Spain, and elsewhere in Europe, as well as from California and Mexico, a large and interesting collection of bells and other objects of artistic worth and historic significance, reminiscent chiefly of the old Spanish missions in America.

MILLER, GEORGE ABRAM (1863-). An American mathematician, born at Lynnville, Pa. He graduated from Muhlenberg College (Pa.) in 1887 and from Cumberland University (Ph.D.) in 1893 and studied later at Leipzig and Paris. He was principal of schools at Greeley, Kans. (1887-88); taught mathematics at Eureka (Ill.) College (1888-93), the University of Michigan (1893-95), Cornell (1897-1901), and Leland Stanford (1901-06). In 1906-07 he was associate professor and thereafter professor of mathematics at the University of Illinois. He taught also in the summer schools of the universities of Chicago (1912) and California (1913); became editor of the *American Mathematical Monthly* and of *School Science and Mathematics*; was coeditor of the *Encyclopédie des Sciences Mathématiques*; and is author of *Determinants* (1892) and coauthor of *Mathematical Monographs* (1911).

MILLER, HENRY (1800-74). An American physician, born at Lexington, Ky. After a short residence in Glasgow and Harrodsburg (both in his native State) he removed to Louisville upon the organization there of a new school of medicine. In this institution he held the chair of obstetrics and diseases of women and children until 1869. In 1859 he was president of the American Medical Association. Miller is author of *Treatise on Human Parturition* (1849) and *The Principles and Practice of Parturition* (1858).

MILLER, HENRY (1860-1926). An American actor and theatrical manager. He was born in London, but when 11 came to America with his parents and settled in Toronto, Canada, where he received a public-school education and made his first appearance on the stage in 1879. After a brief experience in Modjeska's company he came to New York in 1880 and appeared in minor Shakespearean rôles at the Booth Theatre with Adelaide Neilson. Six years later he joined Daniel Frohman's Lyceum Company and became leading juvenile. His best-known early rôles were Clément Hale in *Sweet Lavender* (1888), Colonel Kerchival West in *Shenandoah* (1889), and Claude Melnotte in *The Lady of Lyons* (1890). In 1893 he became a member of Charles Frohman's Empire Theatre Stock Company and remained there as leading man till 1896, playing among other parts John Worthing in *The Importance of Being Earnest* and Michael Faversham in *Michael and his Lost Angel*. After leaving the Empire company he made his first appearance as a star at the Garden Theatre, New York, in 1897. In 1903 he joined Margaret Anglin in a series of co-star performances, playing Dick Dudgeon in *The Devil's Disciple*, Armand Duval in *Camille*, and (in 1906) Stephen Ghent in William Vaughan Moody's *The Great Divide*. After touring America he made his first appearance in England in this last play in 1909. Thereafter he appeared in vari-

ous plays under his own management, including *The Rainbow* (1912) and *Daddy Long-Legs* (1915). Jointly with J. Hartley Manners (q.v.) he wrote *Zira*, and in it played the leading part (1906).

MILLER, HUGH (1802-56). A Scottish geologist and writer, born in Cromarty. He was brought up by two uncles, his father having been drowned when Hugh was five. From his seventeenth to his thirty-second year he worked as a stonemason and from 1834 to 1840 was a bank accountant. In 1829 he published a volume entitled *Poems Written in the Leisure Hours of a Journeyman Mason*. He also made researches in Scottish antiquities, contributed to John M. Wilson's *Tales of the Borders* (1834), and wrote *Scenes and Legends of the North of Scotland* (1835; 3d ed., 1853). However, his studies were mainly geological. His series of articles in this field, collected as *The Old Red Sandstone, or New Walks in an Old Field* (1841; 7th ed., 1907), first appeared in the *Edinburgh Witness*, a paper of which Miller had become editor a year earlier. These articles discussed the author's discovery of fossils in a formation where they had not been thought to exist. His editorial labors during the heat of the disruption struggle so seriously injured his health that for the larger part of 1845-46 he had to give up all literary activity. He resumed the editorship of the *Witness*, which, from 1845, when Robert Fairby and he became joint owners, ceased to represent the Free church. Miller killed himself while insane. His services to science were important, his observation being keen and exact. He was a pioneer in the popularizing of geology. His principal works, besides those already mentioned, are: *First Impressions of England and its People* (1846; 3d ed., 1853), containing many fine specimens of English descriptive prose; *Footprints of the Creator, or the Asterolepis of Stromness* (1847; 3d ed., 1850), designed as a reply to the *Vestiges of the Natural History of Creation: An Autobiography: My Schools and Schoolmasters, or the Story of my Education* (1852); *Testimony of the Rocks* (1857), an attempt to reconcile the geology of Genesis with that of nature. Consult Peter Bayne, *Life and Letters of Hugh Miller* (2 vols., Boston, 1871).

MILLER, JAMES (1776-1851). An American soldier and politician, born at Peterboro, N. H. He was educated for the bar, but in 1808 entered the United States army as major and took part in the frontier warfare, where he displayed great skill and courage. In 1812 he was brevetted colonel for gallantry in the engagement at Brownstown, where he commanded, and in 1814 took part in the Canadian invasion as colonel of the Twenty-first Infantry. In the battles of Chippewa and Lundy's Lane he did substantial service. A gold medal was presented to him by Congress and he was promoted to the rank of brigadier general. In 1819 he resigned from the army. From 1819 to 1825 he was Governor of Arkansas, then a Territory; and from that time until 1849 was collector of the port of Salem, Mass.

MILLER, JOAQUIN. See MILLER, CINCINNATI'S HEINE.

MILLER, JOHANN MARTIN (1750-1814). A German poet, member of the Göttinger Bund. He was born at Ulm, studied theology at Göttingen, and there made the acquaintance of Voss, the idyllist and translator of Homer, and

of Höltz, the lyricist. He contributed to the Göttingen *Almanach* poems which became very popular, especially "Was frag' ich viel nach Geld und Gut." But he is better known for *Siegwart, eine Klostergeschichte* (1776), a sentimental novel, the best of the imitations of Goethe's *Werther*, largely autobiographic and very didactic. His other fiction includes: *Beitrag zur Geschichte der Zärtlichkeit* (1776); *Briefwechsel dreier Freunde* (1776-77); *Geschichte Karls von Burghcim und Emiliens von Rosenau* (1778-79). A collected edition of Miller's poems appeared in 1783 and an autobiography in 1803. Consult Kraeger, *Johann Martin Miller* (Bremen, 1893), and Erich Schmidt, *Charakteristiken*, vol. i (2d ed., Berlin, 1902).

MILLER, JOHN FRANKLIN (1831-86). An American soldier and politician, born in South Bend, Ind. He took a course at the New York State Law School, graduating in 1852, and was elected a Republican member of the Indiana Senate in 1860, but resigned in order to enter the army on the outbreak of the Civil War. He was made colonel of the Twenty-ninth Indiana Volunteers and fought in many of the most important battles in the Mississippi region. For gallantry at the battle of Stone River he was made a brigadier general of volunteers. At Liberty Gap he was severely wounded, but he commanded a division at Nashville and was soon afterward brevetted major general of volunteers. Soon after the war he removed to San Francisco and was for four years collector of the port. He then entered business and was one of the originators and also president of the Alaska Commercial Fur Company. He took an active part in politics, was several times a presidential elector on the Republican ticket, in 1879 assisted in framing a new State constitution, and in 1881 was elected United States Senator from California and served until his death.

MILLER, JOSEPH, or JOSIAS, commonly known as JOE MILLER (1684-1738). An English comedian. With slight interruption he was connected with Drury Lane from 1714 to his death. Great favorites with the town were his Teague in Sir Robert Howard's *Committee* and Sir Joseph Wittol in Congreve's *Old Bachelor*. He was also popular in a score of other roles. So ignorant that he was unable to read, he married that he might have some one to read his parts to him. Though he had no great reputation as a wit off the stage, yet the year after his death appeared a volume of jests ascribed to him under the title *Joe Miller's Jest*s. This pamphlet of 72 pages, containing 247 jests, was compiled by John Mottley for the publisher, T. Read. Why it was fathered upon a poor and illiterate actor is not clear; perhaps by mere accident. The jests are taken in part from earlier collections and in part from current witticisms that had not previously found their way into print. Only three are related of Miller himself. As a whole they are flat; their only piquancy is in their coarseness. But they were exceedingly popular, as is shown by the numerous editions that immediately followed (1st, 2d, 3d, 1739; 4th, 1740; 5th, 1742; 6th, 1743; 7th, 1744; 8th, 1745). The original number of jests, which had increased to 587 in the edition of 1745, continued to grow, until by the middle of the nineteenth century it had reached 1546. Consult the facsimile reprint of the first editions by Bellars (London, 1861) and Hazlitt, *Studies in Jocular Literature* (ib., 1890).

MILLER, JOSEPH NELSON (1836-1909). An American naval officer, born in Ohio. Entering the navy in 1851, he became commander in 1870, captain in 1881, commodore in 1894, and rear admiral in 1897. As executive officer on board the ironclad *Passaic* he was present at the attack upon Fort Sumter in 1863, and for bravery in this and the action against Fort Fisher was highly commended. He represented the Navy Department at the Queen's Jubilee in 1897, in 1898 raised the flag of the United States over Hawaii, and at the time of the Spanish-American War organized the Pacific naval reserves. In November, 1898, he was placed on the retired list.

MILLER, LEWIS (1820-99). An American philanthropist and inventor, born at Greentown, Ohio. He invented and manufactured a mower and reaper and other agricultural machines, which brought him a large fortune. He devised an auditorium for Sunday schools and introduced into Sunday-school services new instrumental music, such as that of piano and cornet. His experience and ideas in the development of religious organization in 1873 suggested to Bishop John H. Vincent the plan of the Chautauqua Assembly, which was adopted, and Miller became president of the Assembly after its foundation the next year. He gave largely to the support of the Assembly and to other enterprises.

MILLER, OREST FEDOROVITCH (1833-89). A Russian literary historian and critic, born in Reval. He studied at the University of St. Petersburg (1851-55) and was professor of early Russian literature there until 1888. His important lectures on *Russian Literature after Gogol* were published in 1874 and his *Slav World and Europe* in 1877. Though a prominent Slavophile, he was less radical than some writers, as is shown by his book on the Slav question (1865). He also wrote *Lomonosov and Peter the Great* in the following year, but became most widely known through his work on the national mythology, entitled *Ilia Muro-mets i Bogartyrvo Kievskoe* (1870).

MILLER, PATRICK (1731-1815). A Scottish inventor, who is asserted by some first to have invented the steamboat. He was born in Glasgow, became a banker, and having accumulated a considerable property, interested himself in maritime inventions. In 1785 he bought the estate Dalswinton in Dumfriesshire and there conducted some experiments with a steamboat of his construction which was propelled by a Symington (q.v.) engine. In 1787 he published a description of one of his vessels under the title *The Elevation, Section, Plan, and Views of a Triple Vessel with Wheels, etc.* Miller was a close friend of Robert Burns. Consult Major General Miller, *A Letter to Bennet Woodcroft Vindicating the Right of Patrick Miller to be Called the First Inventor of Practical Steam Navigation* (London, 1862).

MILLER, RICHARD E. (1875-). An American figure painter. He was born in St. Louis and studied at the School of Fine Arts there (1885-89) and in Paris under Constant and Laurens (1899-1901). The first picture which he exhibited in the Paris Salon (1901) won a gold medal, and he continued to achieve distinction at the Salon. He made Paris his residence; became a Chevalier of the Legion of Honor (1908), a member of the International Society of Painters, Sculptors, and Gravers and

of the Society of American Painters, Paris, and was elected an associate of the National Academy of Design, New York. He is represented in the Luxembourg Gallery, Paris, by the "Old Maiden Ladies" and "Portrait of an Old Woman"; in the Metropolitan Museum of Art, New York, by "The Chinese Statuette"; the Gallery of Modern Art, Rome, "Lady with Fan"; Corcoran Gallery, Washington, "The Boudoir"; and also in the permanent collections of St. Louis, the Carnegie Art Institute, Pittsburgh, the Antwerp Museum, Musée du Petit Palais, Paris, Museum of Christiania, and the modern galleries of Florence and Venice. Among his more recent works are "Springtime," "Before the Mirror" (1913), "La Toilette" (1914), "The Open Window" (1914). Miller became one of the most prominent and influential among American painters residing abroad. His highly modern technique shows impressionistic influence, with delightful color schemes and very subtle and interesting treatment of light and shadow. He excels especially in figure compositions, depicted either out of doors or in rooms flooded with light. Quaint eighteenth-century costumes often add to the charm of his paintings.

MILLER, SAMUEL FREEMAN (1816-90). An American jurist. He was born in Richmond, Ky., graduated in medicine at Transylvania University in 1838, and afterward studied law and removed in 1850 to Iowa, where he became conspicuous in his profession. He ardently supported emancipation of the slaves and became a prominent member of the newly founded Republican party. In 1862 he was appointed an associate justice of the United States Supreme Court by President Lincoln. His decisions gave him a national reputation, and he was especially noted for his opposition to the encroachments of railroad corporations. In 1877 he was a member of the Electoral Commission and in 1887 was the orator of the Centennial Constitution celebration held at Philadelphia.

MILLER, WARNER (1839-1918). An American politician and manufacturer, born at Hannibal, Oswego Co., N. Y. He graduated at Union College in 1860. At the beginning of the Civil War he enlisted in the Fifth New York Cavalry and was promoted to be lieutenant. After leaving the army he became a paper manufacturer at Herkimer, N. Y., and in this business he accumulated a fortune. In 1872 he was elected a delegate to the National Republican Convention, and served as a Republican in the New York Legislature in 1874-75 and in the Forty-sixth and Forty-seventh Congresses (1879-81). He was elected to the United States Senate to fill the place of Thomas C. Platt, who resigned in 1881 as a result of the Conkling-Platt-Garfield fight concerning New York patronage, and served until 1887. As Senator, he was the author of bills granting increased pensions to disabled war veterans, of an eight-hour labor law for letter carriers, and of the "head money" immigration law. He incurred the bitter political enmity of Platt, as was evinced in the Republican National Convention when Harrison was nominated and when Miller was nominated, but defeated, for Governor of New York in 1888. After retiring, Miller gave his attention to his business, becoming an inventor of a wood-pulp process. He was also interested in an effort to construct an interoceanic canal by the Nicaragua route.

MILLER, WILLET GREEN (?1869-). A

Canadian geologist. He was born in the township of North Walsingham, Norfolk Co., Ontario, and was educated at Toronto, Chicago, Harvard, and Heidelberg universities. He was assistant in field geology, Canadian Geological Survey (1891-93); was lecturer and later professor of geology and petrography in Queen's University (1893-1902); and in 1902 was appointed provincial geologist and inspector of mines for Ontario. From 1897 to 1901 he was in charge of the field work in eastern Ontario for the Bureau of Mines. He was elected a member of the Canadian Mining Institute, the American Institute of Mining Engineers, and the Geological Society of America. In 1906 he was a delegate to the International Geological Congress, Mexico City; in 1908-10 he was president of the Canadian Mining Institute; in 1911 he became a fellow of the Royal Society of Canada; and in 1915, for distinguished work, he was awarded the gold medal of the Institution of Mining and Metallurgy, London, England. A large number of his contributions on geological and mining subjects appear in the annual reports of the Ontario Bureau of Mines. He published *Minerals and how they Occur* (1906).

MILLER, WILLIAM (1782-1849). An American religious leader, founder of the sect called Millerites or Second Adventists. He was born in Pittsfield, Mass., but when he was four years old his parents removed to Low Hampton, N. Y., which continued to be his home during most of the remainder of his life. He served as a captain in the American army during the War of 1812, but soon after its close became deeply interested in religion and devoted himself to the study of the Bible. As early as 1818 he came to the conclusion that Christ's second advent had been prophesied for the year 1843, and during the succeeding years became the author of a creed founded on this basis. In 1833 he was licensed to preach, though never ordained, by the Baptist church in Hampton and Whitehall, and in the same year issued a pamphlet entitled *Evidence from Scripture and History of the Second Coming of Christ about the Year 1843; and of His Personal Reign of One Thousand Years* (1833). Soon afterward he began to lecture on the same subject to large audiences in the New England and Middle States. As the year 1843 drew near his followers awaited the second coming with intense excitement. When the year ended he wrote to them confessing his error and acknowledging his disappointment. Later he set Oct. 22, 1844. Even after this second failure many of his disciples remained faithful to him and continued so till the day of his death. The name Adventist was agreed upon in 1845 as the proper designation of his creed. Consult Sylvester Bliss, *Memoirs of William Miller* (Boston, 1853), and James White, *Sketches of the Christian Life and Public Labors of William Miller* (Battle Creek, 1875).

MILLER, WILLIAM (1795-1861). An English soldier, born at Wingham, Kent. Entering the British artillery, he served under Wellington in the Peninsular campaigns of 1811-14 and took part in the operations in Chesapeake Bay (1814). Returning to England, he traveled in Europe for two years and then went to Argentina. Later he joined the Patriot army in Chile and distinguished himself in many battles in the struggle for the independence of that country. In 1821 he went to Peru, where he rendered valuable service to the Patriot cause and rose to the

rank of general of division. He became intimate with Bolívar, was made Governor of Potosí in 1825, and the following year returned to Europe, where he was received with many marks of distinction. In 1843 he was appointed British Consul General in the Pacific, in which post he served till his death. Consult John Miller, *Memoirs of General Miller in the Service of the Republic of Peru* (2d ed., 2 vols., London, 1829).

MILLER, WILLIAM (1834-1912). A Canadian statesman, born at Antigonish, Nova Scotia, and educated at the academy there. Called to the bar in 1860, he became queen's counsel in 1872 and took rank as one of the leaders in his profession. He was elected a Liberal-Conservative member of the Nova Scotia Assembly in 1860 and was prominent in the debates on the Confederation of Canada. Although opposed to the financial part of the scheme, he rendered important service by carrying a resolution authorizing Nova Scotia delegates to frame a Confederation plan in London, England. Thus were secured, under Imperial auspices, changes which made the federal union acceptable to the Nova Scotia Legislature at a time when all appearances were adverse. Miller was called to the Senate in 1867, was Speaker thereof in 1883-87, and remained a member of that body until his death. He was chairman of the standing committees on private bills, railways and canals, and banking and commerce, and also of the joint committee of both Houses of Parliament on the codification of the criminal law. In 1891 he was sworn a member of the Queen's Privy Council for Canada.

MILLER, WILLIAM HALLOWES (1801-80). An English mineralogist. He was born at Vellindre, near Llandoverly, and was educated at St. John's College, Cambridge, where, after graduating in 1826, he became fellow and tutor. In 1832 he was appointed professor of mineralogy and in 1838 was elected a fellow of the Royal Society. In 1838 appeared his famous system of crystal notation in *A Treatise on Crystallography*, the most consistent and adaptable devised up to that time and still in common use. From 1843 to 1854 he was engaged as member of a government commission in replacing the standard of weights and measures, which had been destroyed by fire. In 1870 he served on the Commission Internationale du Mètre and from 1856 to 1873 was foreign secretary of the Royal Society. He contributed frequently to the scientific press and published *The Elements of Hydrostatics and Hydrodynamics* (3d ed., 1843).

MILLER, WILLIAM HENRY HARRISON (1840-1917). An American lawyer and cabinet officer. He was born in Augusta, Oneida Co., N. Y., and graduated at Hamilton College in 1861. He removed in the same year to Ohio, taught school at Maumee for six months, and then enlisted as a private in the Eighty-fourth Ohio Volunteers and was promoted to a lieutenantcy. When his term of enlistment was completed he read law for some time at Toledo in the office of Judge Waite, and in 1863 settled in Peru, Ind., as superintendent of schools. There he was admitted to the bar in 1865. In 1866 he removed to Fort Wayne, where he practiced his profession until 1874, when, having established his reputation, he went to Indianapolis to become the law partner of Benjamin Harrison (q.v.). Their association lasted until the death of the latter, continuing throughout Harrison's administration as President, during which period (1889-93) Miller served as Attorney-General of

the United States, retiring to private practice in 1893. Perhaps his most prominent act while in the cabinet was in connection with the famous Terry case, in which he claimed that it was the constitutional duty of the executive to protect the judiciary.

MILLER, WILLIAM LASH (1866-). A Canadian chemist. He was born at Toronto and was educated at Toronto and Munich universities. For several years he was a demonstrator of chemistry in Toronto University and in 1907 was appointed professor of physical chemistry. He was elected a member of the American Association for the Advancement of Science, vice chairman of the Canadian section, Society of Chemical Industry (1909), and a fellow of the Royal Society of Canada. He published many scientific papers.

MILLERAND, mé'l'ran', ALEXANDRE (1859-). A French statesman and socialist leader, born in Paris, and educated at the Lycee Michelet, Vanves, and the Lycee Henri IV, Paris, and in law, at the University of Paris. He began to practice in Paris in 1881, was counsel to the striking miners of Montceau-les-Mines in 1882; was elected to the municipal council in 1884; and as a Radical Socialist, to the Chamber of Deputies in 1885. In 1889 he became proprietor of *La Voix*, which he made the organ of his personal views. In the Chamber of Deputies Millerand urged many reforms, especially relating to social legislation. He also gained prominence as editor in chief of the *Petite République* (until 1896) and as an impassioned orator. In 1899, as leader of the Parliamentary or Opportunist Socialists, he was made Minister of Commerce in the Waldeck-Rousseau cabinet against the wishes of the Marxian Socialists led by Guesde (q.v.). In this office he did much to pass laws in favor of the working classes. Some of the most important of these were the establishment of one day's rest a week, and a law making 10 hours the maximum day for women and children; he also made many attempts to procure the adoption of compulsory arbitration in industrial disputes. In 1902, just before the cabinet went out of office, a bill was passed making eight hours the maximum day for French miners. Millerand was expelled from the Socialist party because he had taken office in a non-Socialist cabinet. In 1909 he was Minister of Commerce and Postal and Telegraph Service. In the first Briand ministry (1909-10) he held the portfolio of Public Works and in 1912 entered Poincaré's cabinet as War Minister. He won great distinction in this office because of his energy in reorganizing the army and infusing it with enthusiasm. On Aug. 26, 1914, Millerand was again entrusted with the War portfolio under Viviani. On Sept. 23, 1920, he was elected President of France. See SUPPLEMENT.

MILLERITE (named in honor of W. H. Miller). A native nickel sulphide that crystallizes in the hexagonal system, has a metallic lustre, and is of a yellowish color. It occurs usually in capillary crystals in cavities with crystals of other minerals, especially in Bohemia, in Saxony, and in Cornwall, England; in the United States it is found at Antwerp, N. Y., in Lancaster Co., Pa., and especially in geodes in limestone near St. Louis, Mo., and Milwaukee, Wis. Millerite has been made artificially in groups of needle-like crystals.

MILLERSBURG. A village and the county

seat of Holmes Co., Ohio, on Killbuck River, 86 miles south of Cleveland, on the Cleveland, Akron, and Columbus and the Baltimore and Ohio railroads (Map: Ohio, G 4). It has manufactures of foundry and machine-shop products, glassware, flour, brick, lumber, etc. Millersburg is surrounded by a rich agricultural region, carries on a considerable trade in draft horses, and has in its vicinity deposits of coal, iron ore, clay, and shale. The village owns and operates its water works. Pop., 1900, 1998; 1910, 2020.

MILLER'S TALE, THE. One of Chaucer's Canterbury Tales. It is the familiar story of an old husband deceived by a young wife. In this case the husband is a rich old simpleton, a carpenter of Oxford. The source is unknown, but is supposed to be one of the rude jesting stories of the time.

MILLER'S-THUMB (so called from the shape of the head), or RIVER BULLHEAD. A small, spiny-rayed fish (*Cottus gobio*) common in the streams of England and northern Europe and Asia. It rarely reaches 5 inches in length. It is brown above, varying in intensity, as in many fishes, with the color of the bottom, and white beneath. Its disproportionately large, flattened head compared to its body, and the entire absence of scales, give it an ugly appearance. The flesh is reddish when boiled, is said to be of excellent flavor, and is much sought after in some countries. In the United States a related species (*Cottus icталops*) is sometimes called miller's-thumb. It occurs in all clear streams of the Northern and Middle States. These fishes live on small organisms and on fish eggs and are considered a destructive pest by fish culturists, especially in respect to trout eggs. The English fish is a favorite among anglers. Consult T. N. Gill, *Miller's-Thumb and its Habits, Smithsonian Institution, Miscellaneous Collections* (Washington, 1910).

MILLES, mil'les, VILHELM KARL EMIL ANDERSSON (1875-). A Swedish sculptor, born near Upsala and educated in Stockholm and Paris. His father's name was Andersson, Milles being the name of a related family. His works include the Sten Sture monument (near Upsala), the polychrome statue of Gustavus Vasa, seated (Nordiska Museum, Stockholm), portrait busts of J. Kronberg (bronze, Göteborg Museum), O. Lev-ertin (wood, National Museum), Mittag-Leffler (bronze), F. Boberg (bronze, National Museum), and G. Stridsberg (granite, National Museum); studies in animal life, as "Playing Elephants" (National Museum) and "Playing Bears" (granite, entrance to Berzelii Park, Stockholm). Later works are "Vingarna," boy with eagle (1910, bronze, National Museum), and the Scheele statue (1912, Köping). Milles is to be placed in the front rank of Swedish sculptors of his time.—His sister RUTH ANNA MARIA MILLES (1873-), also a sculptor, was born at Valentuna and studied in Stockholm and (1898-1904) in Paris. She is best known for her statuettes, groups, and reliefs of types from Brittany and later Sweden, as: "Redcap and Wolf," "Fisherman's Wife," "Wild Flower," "Young Mother," "Bouquet-Lisa" (Thiels Gallery), "On the Way from Church," "Yvonne," "After Waiting" (National Museum), and "Wood from the Woods."

MILLET (Fr. *millet*, dim. of *mil*, OF. *mil*, *meil*, It. *miglio*, from Lat. *milium*, millet). A name applied to certain cereal and forage grasses of several distinct genera and species. Millets

are extensively used as forage crops in many countries and it has been estimated that they furnish food for about one-third of the inhabitants of the globe. They are widely cultivated for food in India, Japan, and other parts of Asia. In the United States the cultivated varieties of millet may be divided into three groups, viz., foxtail millets, barnyard millets, and broom-corn millets. The foxtail millets, perhaps the most important group, are of very ancient cultivation. They are believed by some writers to have been included in the order of Chinnong, 2700 B.C., requiring certain plants to be sown each year by the Emperor of China in a public ceremony. De Candolle considers this kind of millet a native of China, Japan, and the Indian Archipelago. The most common varieties of this group all belong to one species, *Setaria italica*, and are grown in North America, Europe, India, China, Japan, and north Africa. The barnyard millets include the cultivated varieties of the widely distributed species *Panicum Crusgalli*, or barnyard grass, and also the varieties belonging to other species of the genus *Panicum*, especially *Panicum colonum* and *Panicum frumentaceum*. The varieties derived from *Panicum Crusgalli* are considered the true barnyard millets, and among them a variety of Japanese barnyard millet and the Ankee grass of the south-western United States are the most important. Shama or Sanwa millet, or jungle rice (*Panicum colonum*), a tropical plant, closely allied to true barnyard grass, is a valuable food and forage plant in many tropical and subtropical regions and extensively grown in southern and eastern Asia, but little in the United States. The third group, or broom-corn millets, comprises the varieties of *Panicum miliacum*. This species, universally known to agriculture, has been in cultivation in Europe since prehistoric times and is still the common millet of the Old World. Its origin is very uncertain, but it is probably a native of the warmer regions of Asia. The classification of varieties of this species is based mainly upon the color of the ripe seed—yellow, white, and red. The term Indian or African millet is often loosely applied to certain of the nonsaccharine sorghums, such as durra, Kafir corn, and pearl millet (*Pennisetum typhoidum*), which last is also called Egyptian or cat-tail millet. Efforts have been made to develop the production of the class known as Kafir corn in certain sections of the United States having an insufficient rainfall to insure a reliable maize crop. The quantities produced have been satisfactory but the domestic market has thus far been extremely limited, considerable quantities having been exported to Europe where it is used as food for animals and domestic fowls. See ANDROPOGON; SORGHUM.

Millets are not well adapted to heavy clay or wet soils, but succeed best on fertile friable loams. The preparation of the soil is the same as for other grass crops. In the United States the seed is usually sown late in the spring to prevent the harvest of the millet from interfering with the harvest of the cereals. The seed is usually sown broadcast at the rate of one-half bushel to the acre. It is, however, often drilled. For hay, millet is usually harvested with a mower when the crop has just finished heading, and for the seed with a reaper like cereals a little before it is fully ripe. If harvested when fully ripe there is usually a heavy loss of seed in handling. Where the self-binder is used in har-

vesting this crop the sheaves are bound loosely and put up in shocks to cure. The yield of cured hay per acre ranges from four to six tons and the yield of seed from 40 to 50 bushels. According to the thirteenth census the United States produced, in 1909, 1,743,887 tons of millet hay and 588,270 bushels of seed, a decrease in the crop of about 25 per cent compared with 1899. This crop is practically free from attacks of insects and plant diseases.

Feeding Value. Millet is valuable principally as hay and as a soiling crop. It is also useful for silage. The ripened seeds are seldom fed to stock, but are much used as food for poultry and birds. If used as stock food they should be crushed or ground. The seed of broom-corn millet has found more favor in the United States as a cattle feed than that of other varieties. German millet cut when the heads are well filled but the seeds still soft has the following percentage composition: water, 71.7; protein, 2.7; fat, 0.5; nitrogen-free extract, 14.3; crude fibre, 9.3; and ash, 1.5. German millet hay: water, 7.7; protein, 7.5; fat, 2.1; nitrogen-free extract, 49; crude fibre, 27.7; and ash, 6. Other millets fresh and cured resemble in composition the examples quoted more or less closely. The average percentage composition of millet seed follows: water, 14; protein, 11.8; fat, 4; nitrogen-free extract, 57.4; crude fibre, 9.5; and ash, 3.3. In the case of barnyard millet hay 57.4 per hundredweight, of the protein 63.7 per hundredweight, of the nitrogen-free extract 51.6 per hundredweight, and of the crude fibre 61.6 per hundredweight were on the average found to be digestible. Millet hay is a useful coarse fodder for cows, but not more than six or eight pounds should be fed daily. When fed to lambs care should be exercised, as millet hay causes scours unless fed in small quantities. It has been observed that when horses were fed millet hay exclusively as coarse fodder, painful conditions called millet disease were induced. It is believed that the trouble may be avoided by using this hay in limited quantities, and not continuously. It is also possible that millet grown in some regions is harmless, while that grown in others is harmful. The plant has been used for farm animals since very early times, and generally speaking has proved a satisfactory feeding stuff. See Colored Plate of CEREALS.

Consult: T. A. Williams, *Millets* (Washington, 1899); C. R. Ball, *Pearl Millet* (ib., 1903); *United States Department of Agriculture, Year Book for 1898 and Farmer's Bulletin 101*.

MILLET, mé'lâ', AIMÉ (1819-91). A French sculptor and painter. He was born in Paris, received his first instruction in painting from his father, and studied sculpture with David d'Angers, and after 1852 gave up painting entirely. For his work in sculpture he won a gold medal at the exposition of 1889. His most ambitious work was the erection for Napoleon III in 1865 of a colossal copper statue of Vercingetorix at Alise-Sainte-Reine. His statues adorn several public buildings in Paris, among them an "Apollo" in bronze at the New Opéra. His mythological statues and groups include "Bacchante" (1885); "Narcissus" and "Ariadne," acquired by the state. Among his portrait statues are those of Denis Papin at Blois, Chateaubriand at St. Malo, Gay-Lussac at Limoges, and Edgar Guinet at Bourg. He executed many portrait busts and statues in marble and bronze. Although realistic in character, his art is theatri-

cal in pose. Consult Dumesnil, *Aimé Millet* (Paris, 1891).

MILLET, FRANCIS DAVIS (1846-1912). An American mural and genre painter, war correspondent, illustrator, and author. He was born at Mattapoisett, Mass., Nov. 3, 1846, took part in the Civil War as a drummer and assistant surgeon, and graduated at Harvard (A.B., 1869; A.M., 1872). He was a pupil at the Royal Academy of Fine Arts at Antwerp (1871-72), and also studied in France and Italy, at the same time writing illustrated articles for American periodicals. During the Russo-Turkish War (1877-78) he was engaged by the *New York Herald*, the *London Daily News*, and the *London Graphic* as war correspondent, attached to General Skobelev's staff. His stories from the front were accompanied by sketches. He was director of the decorations and functions of the World's Fair at Chicago in 1893. The year 1898 saw him in the Philippines as the correspondent of the *London Times* and *Harper's Weekly*. Millet is now best known for the mural paintings to which he devoted the latter years of his life. The greatest of these is probably the "Evolution of Navigation" in the Custom House at Baltimore, Md.; but there are other important examples of his work in this field in the Post Office, Cleveland, Ohio; the Governor's room of the Minnesota State Capitol; the Hudson County Court House, Jersey City; the Essex County Court House, Newark, N. J.; the Supreme Court at Madison, Wis. The same strong synthetic sense, accuracy of detail, and harmonious grouping displayed in his decorative works also distinguishes his highly finished genre paintings of England in the eighteenth century and of classic Rome and Greece, in which costume and interior are studied with much detail, showing the influence of the Dutch school. His chief easel paintings include: "At the Inn," Union League Club, New York City; "A Cozy Corner" and "An Old-Time Melody," both in the Metropolitan Museum; "Between Two Fires," Tate Gallery, London; portraits of Mrs. Millet and President Butler of Columbia University (1906). He was prominently identified (1905-06) with the organization and endowment of the American Academy at Rome (q.v.), of which he was the first secretary. He was elected a member of the National Academy of Design (1885) and of the American Academy of Arts and Letters and an honorary member of the American Institute of Architects; was decorated with Russian and Rumanian military orders and medals for bravery; and received medals for paintings shown at Paris (1889), Chicago (1893), and Buffalo (1901). His literary works include: *Capillary Crime and Other Stories* (1892); *The Danube* (1892); *The Expedition to the Philippines* (1899). Millet lost his life in the sinking of the *Titanic*, April 15, 1912. For many years he had lived in Worcestershire, England. In 1913 a fountain was erected in Washington, D. C., in memory of Millet and of Archibald W. Butt (q.v.). Consult Beckwith, Baxter, Maynard, Blashfield, and Coffin, *Art and Progress*, vol. iii (Washington, 1912).

MILLET, mé'lá', JEAN FRANÇOIS (1814-75). A French genre and landscape painter of the Barbizon group, the greatest of all peasant painters. He was born at Gruchy, near Gréville (Manche), Oct. 4, 1814, the eldest son of a Norman peasant. His father, who exercised a great influence upon Millet's life and character,

was a man of refined and deeply religious nature and of musical tastes, being cantor in the village church. Under the tuition of the village priest he received an elementary education, even mastering Greek, but his early years he spent on the farm, trying, during hours of rest, to draw the familiar scenery and life about him. His father took him to the neighboring town of Cherbourg, where he studied under Mouchel, a pupil of the school of David, and Langlois. In 1837, aided by a small gift of money from the council general of the department and by a small pension granted by the town council of Cherbourg, Millet went to Paris. He entered the studio of Delaroche, but, unable to endure his master's conventional methods, and constrained by poverty, he soon withdrew. With Marolle, a friend, he opened a little studio, giving his evenings to study and his days to painting cheap portraits and pastel imitations of Boucher and Watteau. He won some recognition with a portrait in the Salon of 1840, but soon returned to Normandy, where he married (1841). There he supported himself by painting signboards, and also produced "Sailors Mending a Sail" and other genre works. In 1842 he returned to Paris and in 1844 attracted the favorable attention of artists by his "Milkwoman" and "Riding Lesson." On the death of his wife he returned to Normandy, but remarried and came again to Paris in 1845. After a series of religious and classical subjects, none of which attained success, he at last found himself in the "Winnower" (1848, Louvre), his first important picture, bought by Ledru-Rollin, the Minister of State during the revolution of 1848, in which Millet took part.

In 1849 he abandoned Paris for the village of Barbizon, which he made his permanent home. Here the Norman peasant, as he called himself, was surrounded by scenes he loved, with incomparable models for the peasant pictures to which he henceforth devoted himself. "The Sower" (1850, Vanderbilt collection, Metropolitan Museum, New York) was followed by "Man Spreading Manure" (1852); "The Reapers" (1853); "A Peasant Grafting a Tree" (1855); "The Gleaners" (1857, Louvre), one of his very best works; "The Angelus" (1857, Louvre); "Death and the Woodcutter" (1859, Copenhagen Gallery); "Woman Feeding her Children" (La Becquée, 1860), in the Lille Museum; and others, all produced while he was hampered by illness and debts. In 1860 he bound himself by contract to give all his work for three years for 1000 francs a month, but the contract was dissolved in six months. To this period belong "The Sheep Shearing" (1860); "Woman Feeding Child," "The Sheep Shearer," "Waiting" (all in 1861); "Potato Planters" (1862); "The Wool Carder" (1863); and "The Man with the Hoe" (1863, San Francisco Museum). From 1860 his reputation was regarded as established, and after 1863 he no longer suffered want. In 1864 he exhibited "The Shepherdess" (Louvre) and "Peasants Bringing Home a Calf"; in 1865 he produced some decorative work. At the Paris Exposition of 1867 he received a medal of the first class and in 1868 the ribbon of the Legion of Honor. Driven from Barbizon by the Franco-Prussian War, Millet repaired to Cherbourg and did not return until late in 1871. He was deeply affected by the death, in 1867, of his friend Rousseau, with whom, of all others, he was most intimate. Although the state of his health,

which had been failing for some time, curtailed the hours of work, he continued to paint until December, 1874, when fever set in and he died on Jan. 20, 1875.

He was one of the artists selected by the government to decorate the Panthéon, but did not live to complete the commission. A number of important works are owned in the United States, among which are: "The Sower" and the "Water Carrier," "The Shepherdess," "At the Well," "The Knitting Lesson," "Hunting in Winter," the water color "Shepherd and Dog," and "Girl Raking Hay," all in the Metropolitan Museum, New York; "The Grafter," "Shepherdess," and "Water Carrier" (all three belonging to William Rockefeller); "The Turkey Keeper" (C. A. Dana, New York); "A Shepherdess Seated," "Homestead at Gréville," "Harvesters Resting," "Portrait of himself," and others in the Boston Art Museum; the "Planters" (Quincy Shaw collection, Boston); "Potato Harvest," "Sheepfold," "Breaking the Flax," and five other works in the Walters collection, Baltimore. Although Millet's paintings began to increase in value before his death, his family was left in straitened circumstances and was pensioned by the government. His principal pictures have been etched and engraved. Himself a peasant, living the peasant's life, he painted his class as has never been done before or since. Omitting the accidental, he rendered only the typical, and his great shadowy figures seem inevitably a part of the earth. It was the master's custom to paint from memory, using his admirable sketches but no models, and to this is partially due the simplicity and breadth with which he treated his subjects.

Equally famous with Millet's paintings are many of his drawings, such as his own portrait (1848); "Woman Feeding Chickens"; "Shepherd with Flock"; "The Newborn Lamb"; "Laundresses on the Shore"; "First Steps." His pastels, too, are much prized; good examples are the "Vine Dresser Resting" and "Woman Churning." All show a good draftsman, with a fine feeling for form. His color is sad in tone, gray and brown usually prevailing; and he achieved harmony by a masterly treatment of light and atmosphere. The landscape background and the animals of his paintings are the equals of those done by the greatest specialists in these branches. Among the best of his pure landscapes are "Church of Gréville," "Spring," and "Winter"; the first two are in the Louvre, which, since the acquisition of the famous Chauchard collection, contains in all 21 paintings by Millet. He was also an etcher of great power, as is evident from his 13 original plates of subjects of peasant life, as well as from a number of others after his paintings. His designs for woodcuts, generally engraved by his two brothers, show great originality, being executed in bold, coarse outlines, more like those of the old German masters than nineteenth-century etchings. Monuments to Millet have been erected in Cherbourg and Gruchy, and a bronze plaque attached to a rock at the entrance to the forest of Fontainebleau is dedicated to him and Rousseau.

Bibliography. Much the best biography of Millet was written by his friend Alfred Sensier, *La vie et l'œuvre de Jean François Millet* (Paris, 1881; abridged Eng. trans., Boston, 1896). Consult also: Alexandre Piedagnel, *Jean François Millet: souvenirs de Barbizon* (Paris, 1876);

MILLET, PIERRE (1635-1708). A Canadian pioneer missionary. He was born in Bourges, France, was educated for the Roman Catholic priesthood, and came to Canada in 1667. The following year he went to New York as a missionary to the Onondaga Indians. In 1672 he undertook a mission to the Oneidas in that colony, where he labored devotedly. He returned to Canada, met Governor Denonville at Catarqui in 1686 and, in consequence of the Governor's expedition against the Iroquois, was suspected, though unjustly, of instigating it. At first the Oneidas, one of the Iroquois tribes, were hostile and sent a war party which captured him at Catarqui in 1689 and took him back a prisoner to their country. They tortured him and threatened to kill him, but he was finally set free and adopted into their tribe, where he remained until 1694. In that year he returned to Quebec, where he died.

MILLET BEER. See BEER.

MILLI, mē'lè, GIANNINA (1825-88). An Italian poetess. She was born at Terama and when but a child of five years is said to have composed verses. When 17 or 18 years of age she became a pupil of the poet Regaldi, the greatest of Italian improvisators, and soon developed considerable power in improvising popular religious and amatory verses. Medals were awarded her, and after her trips through the principal Italian cities (1857-60) a pension was bestowed upon her. She was appointed inspector of elementary schools for girls and superintendent of the normal school for young women in Rome. Her poems appeared in two volumes in 1862-63.

MILLIGAN, EX PARTE. The title of an important decision rendered by the Supreme Court of the United States in 1866, growing out of the events of the Civil War. The precise question raised was whether a citizen domiciled in a State where peace prevails, but which is adjacent to the theatre of war, may be deprived of the right of trial by jury and be subjected to trial before a military commission composed of army officers. The case grew out of the arrest of one Milligan, a citizen of Indiana, by a United States military officer in 1864 on charges of conspiracy, disloyal practices, inciting insurrection, and giving aid and comfort to the enemy. He was tried before a military commis-

MILLET
"THE GLEANERS," FROM THE PAINTING IN THE LOUVRE, PARIS

sion at Indianapolis, was found guilty, and was sentenced to be hanged. His counsel thereupon filed in the Circuit Court of the United States a petition for a writ of habeas corpus, denying the jurisdiction of the military commission on the ground that the civil courts in Indiana were open and unobstructed in the performance of their duties, that a United States grand jury which was then in session failed to find a bill of indictment, that the plaintiff was a civilian in no way connected with the military service, and that he was not a resident of a rebel State. The case was finally carried to the Supreme Court of the United States, where it was held that a military commission organized during the war in a State not invaded or in rebellion, and where the Federal courts were open and unobstructed, had no jurisdiction to try, convict, or sentence for a criminal offense a citizen who was neither a resident of a State in rebellion nor a prisoner of war nor a person in the military or naval service, and that Congress had no power to confer such authority on it. This opinion was rendered by a bare majority of the court, a vigorous dissenting opinion being delivered by Chief Justice Chase, in which three other justices concurred. The decision is given in *Wallace's Reports*, vol. iv. See MILITARY LAW; MARTIAL LAW.

MILLIGAN, GEORGE (c.1861-). A Scottish biblical scholar, son of William Milligan. He was educated at Aberdeen, Edinburgh, Göttingen, and Bonn; was minister of St. Matthew's, Morningside, and of Caputh; and in 1910 became regius professor of divinity and biblical criticism in Glasgow University. He published: *History of the English Bible* (1895); *The Lord's Prayer* (1895); *The Theology of the Epistle to the Hebrews* (1899); *The Twelve Apostles* (1904); *St. Paul's Epistles to the Thessalonians* (1908), Greek text, introduction, and notes, with special study of syntax and style; *Selections from the Greek Papyri* (1910); *The New Testament Documents: Their Origin and Early History* (1912), the Croall lectures for 1911-12; *The Vocabulary of the Greek Testament* (1914 et seq.), with J. H. Moulton.

MILLIGAN, ROBERT WILEY (1843-1909). An American naval officer. He was born in Philadelphia, entered the United States navy as third assistant engineer in 1863, and was regularly promoted to chief engineer in 1892, commander in 1899, and captain in 1902. During the Civil War he participated in both battles of Fort Fisher, and in the capture of Petersburg and Richmond, and during the Spanish-American War he was chief engineer of the *Oregon* on her famous run from the Pacific to the Atlantic coast and in the battle of Santiago. He served as chief engineer of the Norfolk Navy Yard from 1899 to 1905, when he was advanced to the rank of rear admiral and retired.

MILLIGAN, WILLIAM (1821-93). A minister of the Established church of Scotland, born in Edinburgh. In 1839 he graduated from St. Andrews University. He stood by the "Auld Kirk" at the disruption (1843), and was ordained minister to the Parish of Cameron, Fife, the following year. He studied in Germany from 1845 to 1846 and was placed at Kilconquhar from 1850 until 1860, when he was asked to occupy the newly created chair of biblical criticism in Aberdeen University. He assisted in the revision of the New Testament in 1870 and published works on the *Higher Education of*

Women (1878); *The Resurrection of Our Lord* (1881; new ed., 1905); *Commentary on the Revelation* (1883); *Baird Lectures on the Revelation of St. John* (1886); *Elijah* (1887); *The Resurrection of the Dead* (1890); *Aims of the Scottish Church Society* (1892); besides a notable article for the *Encyclopædia Britannica* on the Epistle to the Ephesians (1879). He was sent to the United States Presbyterian General Assembly (1872) as a delegate from the corresponding body in Scotland.

MILLIKIN UNIVERSITY. See JAMES MILLIKIN UNIVERSITY.

MILLIN, mé'lân', AUBIN LOUIS (1759-1818). A French archæologist, born in Paris. His first literary attempts were translations from the German and English, which were published in the *Mélanges de littérature étrangère* (1785-86). His protest against the excesses of the Revolution made it necessary for him to flee from Paris, and he was imprisoned for a year in St. Lazare on his return. In 1795 he was placed in charge of the cabinet of antiques and medals in the National Library, was instrumental in the creation of a chair of antiquities, and the same year undertook the direction of the *Magazin Encyclopédique*. Much of his voluminous writing on his special subject appeared in this periodical, which, in 1817, became the *Annales Encyclopédiques*, and he published also *Antiquités nationales* (1790-98); *Introduction à l'étude des médailles* (1796); *Monuments antiques inédits* (1802-04); *Dictionnaire des beaux-arts* (1806); *Histoire métallique de la révolution française* (1806). His travels in Italy and the south of France in search of antiques provided material for *Voyage dans les départements du midi de la France* (1807-11); *Peintures de vases antiques* (1808-10; new ed., 1891); *Voyage en Savoie, au Piémont, dans le Milanais* (1816-17).

MILLING MACHINE. See METAL-WORKING MACHINERY.

MILLINOCK/ET. A village in Penobscot Co., Me., 83 miles by rail north of Bangor, on the Bangor and Aroostook Railroad (Map: Maine, D 3). The manufacture of paper constitutes the chief industry. Some timber is found in the surrounding region. Pop., 1910, 3368.

MIL/LIPEDE. A myriapod of the order Chilognatha (or Diplopoda) having a dorsally convex body composed of many segments, all of which, except the first four, bear each two pairs of legs, and lacking maxillipes. See CENTIPEDE; MYRIAPODA.

MILLIS, JOHN (1858-). An American officer of engineers, born at Wheatland, Mich. He graduated, with first rank, from the United States Military Academy in 1881, and served at Willets Point, N. Y. (1881-83), and on lighthouse duty, especially in experiments with electric lighting (1883-90). Millis was charged with the preparation of the lighting of the Bartholdi Statue in New York harbor. From 1890 to 1894 he managed Federal improvements in the Mississippi levees and New Orleans harbor; then for four years was chief engineer of the Lighthouse Board; and in 1900 was delegate to electrical, physical, and navigation congresses in Paris during the Exposition, and was sent to Egypt to report on the Assuan Dam. After his return to America he was ordered to Seattle to construct fortifications in Puget Sound and government improvements in Washington, Idaho, and Montana. In 1905-07 he had charge of all

fortification construction in the Philippine Islands, conducted the river and harbor improvements in Indiana and Ohio and on Lake Erie in 1908-12, and was then detailed for special duty under the Bureau of Lighthouses. He was promoted to colonel of engineers in 1910.

MILLÖCKER, mil'lë-kër, KARL (1842-09). An Austrian composer of light opera. He was born in Vienna and received his musical education in the conservatory of that city. In 1864 he was appointed kapellmeister at the Graz Theatre and from 1869 to 1883 occupied a similar position at the Theater an der Wien in Vienna. His music is marked by its spontaneous melodiousness and sprightly instrumentation. The principal published works include: *Der todte Gast and Die beiden Binder* (1865); *Diana* (1867); *Die Fraueninsel* (1878); *Der Regimentstambour* (1869); *Drei Paar Schuhe* (1870); *Die Musik des Teufels* (1870); *Das verrucnschene Schloss* (1878); *Apajune, der Wassermann* (1880); *Die Jungfrau von Belleville* (1881); *Der Bettelstudent* (1881); *Gasparrone* (1884); *Der Viceadmiral* (1886); *Die sieben Schwaben* (1887); *Der arme Jonathan* (1890); *Das Sonntagskind* (1892); *Der Probekuss* (1895); *Das Nordlicht* (1897).

MILLOM. A town in Cumberland, England, 9 miles northwest of Barrow. It is situated on the west coast of Duddon estuary and has a shallow tidal harbor. It numbers among its antiquities an early Norman church and the eleventh-century Millom Castle. The most productive mines of red hematite ore in England are worked in the vicinity, and it has numerous blast furnaces. The town owns its markets, water and gas works, and maintains a library, technical schools, recreation grounds, and isolation hospital. Pop., 1901, 10,426; 1911, 8612.

MILLO MAIZE. See ANDROPOGON; SORGHUM.

MILL ON THE FLOSS, THE. A novel by George Eliot (q.v.), published in 1860.

MILLS, ALBERT LEOPOLD (1854-1916). An American soldier, born in New York City. He graduated at the United States Military Academy in 1879, was appointed second lieutenant of the First Cavalry, was stationed at Fort Walla Walla, Washington Territory (1879-82), and engaged in frontier duty elsewhere. He saw active service against the Crows in 1887 and against the Sioux in 1890. He became first lieutenant in 1889. He was professor of military science and tactics at the State Academy, Charleston, S. C., for a year (1886-87), held an appointment at the United States Infantry and Cavalry School, Fort Leavenworth, Kans., from 1894 until 1898, and in the Spanish-American War participated in the Santiago campaign as captain and assistant adjutant general of volunteers. He was voted a medal by Congress in 1898, for his services near Santiago. In August, 1898, he was made superintendent of the United States Military Academy, West Point, with the rank and pay of colonel, and in October of the same year was promoted to the regimental rank of captain. In 1904 he was made brigadier general and in 1906 was detached from the command of the Military Academy, the scope and general efficiency of which had broadened considerably under his administration, and was assigned to duty in the Philippine Islands. In 1909 he returned to the United States to take command of the Department of the Gulf, and in 1912 was for part of a year president of the Army War College. After

September of 1912 he served as chief of the division of militia affairs on the general staff.

MILLS, CHARLES KARNEER (1845-). An American neurologist, born in Philadelphia and educated at the Central High School and the medical department of the University of Pennsylvania. He began to practice in 1869; was professor of diseases of the mind and nervous system at the Philadelphia Polyclinic (1883-98) and clinical professor of nervous diseases at the Women's Medical College of Pennsylvania. At the University of Pennsylvania he served as professor of mental diseases and medical jurisprudence (1893-1901), clinical professor of nervous diseases (1901-03), and professor of neurology after 1903. He attained a high reputation as an alienist. Besides monographs on mental and nervous strain, he published: *Practical Lessons in Nursing* (new ed., 1904); *Physiology and Hygiene* (rev. ed., 1904); *The Nursing and Care of the Nervous and Insane* (new ed., 1912); and edited a valuable *Treatise on the Nervous System and its Diseases* (1894).

MILLS, CLARK (1815-83). An American sculptor, born in Onondaga Co., N. Y. In his youth he followed the trade of a plasterer, at the same time modeling ideal heads in clay. Although entirely self-taught and without knowledge of professional methods, in 1846 he completed a marble bust of John C. Calhoun, which was purchased by the city of Charleston for the city hall. In 1848 he furnished a design for an equestrian statue of General Jackson, to be placed in Lafayette Square, Washington. There being no bronze foundry for such work in the United States, Mills erected in Washington an experimental foundry, where in 1852 he succeeded in producing a perfect cast. It was formally accepted Jan. 8, 1853, and, although without artistic value, is interesting as the first equestrian statue in American sculpture. He was next engaged on the colossal equestrian statue of Washington, which was formally unveiled in the national capital Feb. 22, 1860. Mills's last work was the casting (1863) of Crawford's colossal statue of Liberty, which crowns the dome of the Capitol at Washington. Compared with present-day sculpture the work of Mills seems inferior and mechanical, but it marks a stepping-stone in the advance of American art.

MILLS, DARIUS OGDEN (1825-1910). An American financier and philanthropist, born at North Salem, N. Y. He was a clerk in New York City and served as a bank cashier at Buffalo, N. Y., in 1847-49. In 1849 he went to California, where he became a merchant and dealer in exchange at Sacramento and founded the bank of D. O. Mills & Co. In 1864-67 he was president of the Bank of California, San Francisco; and after the failure of that institution under his successor Mills reestablished it on a sound basis. In 1880 he moved to New York City, where he erected the Mills Building on Broad Street and where he became identified with a variety of interests, as trustee of the Metropolitan Museum of Art, the American Museum of Natural History, and the American Geographical Society, and as president of the New York Botanical Gardens. In 1868-90 he was regent and treasurer of the University of California, in which he endowed a chair of philosophy; and he was also trustee of the Lick estate and Observatory. Mills gave extensively to philanthropic objects. The three Mills hotels

in New York, where poor but self-respecting men may obtain meals and lodgings at a nominal price, stand as a monument to his wise benevolence. They proved especially successful and attracted wide attention among charity workers and social investigators. At the time of his death Mills possessed a fortune of \$35,000,000. His daughter married Whitelaw Reid (q.v.).

MILLS, DAVID (1831-1903). A Canadian statesman and jurist. He was born in the township of Orford, Kent Co., Ontario, was educated at the local schools, and graduated in law at the University of Michigan in 1855. After teaching for a time he was school superintendent for Kent County until 1865. Entering political life at Confederation in 1867, he was elected Liberal member for Bothwell in the first Dominion Parliament and, with the exception of one legislative session (1882), retained his seat in the House of Commons until 1896. He edited the London (Ontario) *Daily Advertiser* in 1882-87, was called to the Ontario bar in 1883, and was soon afterward employed by the Ontario government in several important cases. He became an authority on constitutional and international law and in 1888-1900 was professor of these subjects in Toronto University. He was Minister of the Interior (1876-78) in the administration of Alexander Mackenzie (q.v.), was called to the Senate in 1897, and was Minister of Justice (1897-1901) in the administration of Sir Wilfrid Laurier (q.v.). In 1901 he was appointed a judge of the Supreme Court of Canada, which position he retained until his death. As a private member of Parliament (1879-96) Mills advocated measures for better securing the independence of the electorate, and in 1895 made a motion in the House of Commons to reform the Senate. He published: *Report on the Boundaries of Ontario* (1873); *The Canadian View of the Alaskan Boundary Dispute* (1899); *The English in Africa* (1900); and many magazine articles on political and economic subjects.

MILLS, HIRAM FRANCIS (1836-). An American hydraulic and sanitary engineer, born at Bangor, Me. After graduating C. E. from the Rensselaer Polytechnic Institute in 1856 he was engaged in engineering work on the Bergen (N. J.) tunnel of the Erie Railroad (1858), on the Brooklyn water works (1859), at Cohoes, N. Y. (1859), and, under the noted hydraulic engineer, James B. Francis, at Lowell, Mass. (1860-63). For the next six years he was employed on important railroad, dam, and water-power works, including the Hoosac Tunnel on the Fitchburg Railroad, Massachusetts. In 1869 he began a long career in the control of water power on the Merrimac River, first at Lawrence and later at Lowell as well. He served as chief engineer of the Essex Company at Lawrence after 1869, and as consulting engineer of the Proprietors' Locks and Canals at Lowell in 1893, becoming chief engineer in 1894. In 1901 he was appointed consulting engineer of the Boston Metropolitan Water and Sewerage Board. From 1886 to its dissolution in 1914 he was engineer member of the Massachusetts State Board of Health, chairman of its committee on water supply and sewerage, and directed the Lawrence Experiment Station investigations of water and sewage purification, known throughout the sanitary world. In 1892-93 he designed and built the slow sand filters of the water works of Lawrence, Mass.; these marked a new

era in water purification. After 1868 he served as consulting engineer on various other works in the United States and Mexico.

MILLS, JAMES (1840-). A Canadian educator and railway administrator. He was born near Bond Head, Ontario, and was educated at Victoria University, where he graduated at the head of his class in 1868. He taught successively at Stanstead (1868-69), Cobourg (1869-72), and Brantford (1873-79), gaining high rank in his profession. He was appointed president of the Ontario Agricultural College at Guelph in 1879, in which position he remained for 25 years, bringing the college to a high state of efficiency. As its president and the organizer for 10 years of farmers' institutes he did eminent service for agricultural education in Ontario. He was a member of the San José Scale Commission (1899). In 1904 he was appointed a member of the Board of Railway Commissioners for Canada. He was a member of the board of regents, Victoria University (1890-1910), and was also appointed a senator of Toronto University. With Thomas Shaw he wrote *First Principles of Agriculture* (1890).

MILLS, LAWRENCE HEYWORTH (1837-1918). An English Orientalist. He was born in New York City and graduated at the University of the City of New York (now New York University) in 1857. He then studied for orders at the Fairfax County Episcopal Seminary near Alexandria, Va., and was ordained in 1861, after which he held a charge in Brooklyn until 1867. Retiring from the ministry, he went to Europe in 1872, where he devoted himself first to a study of Gnosticism and then to the Avesta, which was to prove his life work. In 1887, at the request of Max Müller, he went to Oxford, where in 1898 he was made professor of Zend philology. Mills's researches were concerned mainly with the older portion of the Avesta texts, the Gâthâs (q.v.), which he studied exhaustively, adhering in the main to the system of the traditional school of interpretation. He also published many contributions on the early phases of Zoroastrianism, and must be regarded as one of the foremost of Iranian scholars. Among his works are: "Zend Avesta, part iii," in Müller, *Sacred Books of the East*, vol. xxxi (Oxford, 1887); *Study of the Five Zarathushtrian (Zoroastrian) Gâthâs* (1894); *Gâthâs of Zarathushtra (Zoroaster) in Metre and Rhythm* (1900); *Dictionary of the Gâthic Language of the Zend Avesta* (1902-14); *Zoroaster, Philo, the Achæmenids, and Israel* (2 vols., 1904-06); *Avesta Eschatology Compared with the Books of Daniel and Revelations* (1908); *Yasna I, with Avesta, Sanskrit, Pahlavi, and Persian texts* (1910); *Our own Religion in Ancient Persia*, lectures delivered at Oxford (1913); *Lore of Avesta in Catechetical Dialogues* (1914).

MILLS, ROBERT (1781-1855). An American engineer and architect. He was born in Charleston, S. C., and studied under Benjamin H. Latrobe. He erected several customhouses and marine hospitals, and in 1820 was appointed State architect and engineer of South Carolina. In 1836 President Jackson made him the official architect of the United States government and supervising architect of the Capitol; this office he held until 1851. Under this and the next administration Mills designed and had charge of the erection of the Treasury Building, the General Post Office, the Patent Office Building, and the National Washington Monument.

MILLS, ROGER QUARLES (1832-1911). An American soldier and statesman, born in Todd Co., Ky. He removed to Palestine, Tex., in 1849, studied law while acting as clerk in the post office, and at 20 was admitted to the bar. He was elected to the Texas House of Representatives in 1859, but entered the military service of the Confederacy at the outbreak of the Civil War and took part in the battles of Arkansas Post (Jan. 11, 1863), Chickamauga (Sept. 19-20, 1863), where he commanded a brigade, New Hope Church (May 27, 1864), and Atlanta (July 22, 1864). In 1873 he was elected to Congress, where he continued as a member of the House until 1892, when he was chosen to fill an unexpired term in the Senate, and the next year was reelected for the full term. As a Representative, he bitterly opposed the Electoral Commission resolution, claiming that Tilden was constitutionally elected. In 1884-88 he was chairman of the House Committee on Ways and Means, in which capacity he drafted in 1888 the Cleveland administration tariff act, the so-called Mills Bill, which made important reductions in existing rates and was famous as a party measure. Since the Republicans controlled the Senate, it failed of enactment, as was expected.

MILLS, SAMUEL JOHN (1783-1818). An American missionary. He was born at Torrington, Conn., April 21, 1783, and graduated at Williams College in 1809. While in college he first suggested to a group of students the project of foreign missions, at a meeting for prayer by a haystack near the college. After spending a short time in the study of theology at New Haven he entered Andover Theological Seminary in 1810. With Judson, Hall, Newell, and Nott he united in a memorial to the General Association of Massachusetts (Congregational), which resulted in the formation of the American Board of Commissioners for Foreign Missions. He was licensed to preach in 1812 and spent two years in mission work in the Southern and Western States. He suggested the formation of a national Bible society, which resulted in the organization of the American Bible Society. To him was due the formation of the United Foreign Mission Society. Through his exertions in conjunction with Dr. Finley the American Colonization Society was formed in 1817 and he was appointed with Dr. Burgess to visit England in behalf of the society and to explore the west coast of Africa for a suitable site for a colony of colored people from America. He sailed in November, 1817, and arrived on the coast March 12. He embarked for the United States, May 22, 1818, and died at sea June 16. He is called the "father of foreign missions in America." Consult the memoir by Spring (New York, 1854), and T. C. Richards, *Samuel J. Mills* (Boston, 1906).

MILLS, SEBASTIAN BACH (1838-98). An Anglo-American piano virtuoso and teacher, born at Cirencester in England. He was trained by his father and under Potter and Sterndale Bennett and was regarded as the most precocious child musician in Great Britain. He completed his musical education under Moscheles, Plaidy, and the other distinguished teachers of the Leipzig Conservatory. After leaving Leipzig he studied for a period under Liszt, who held him in high estimation. He returned for a little while to England, where he held the appointment of organist at the Roman Catholic cathedral at Sheffield (1855). Three

years later he returned to Germany and played at a Gewandhaus concert (Dec. 2, 1858). The following year he appeared in New York under the auspices of the Philharmonic Society and thereafter made his home in America. He was very successful as a teacher and as a concert pianist was as popular in Germany as in the United States. His compositions are few and comparatively unimportant. He died at Wiesbaden.

MILLS, THOMAS WESLEY (1847-1915). A Canadian physiologist and educator. He was born at Brockville, Ontario, and was educated at Toronto University, and in medicine at McGill University, afterward studying in England and Germany. At McGill University he was successively demonstrator of (1882-84), lecturer in (1884-86), and professor of (1886-1910), physiology. In 1910 he was made professor emeritus of physiology in the same university. He was one of the founders of the Society for the Study of Comparative Physiology (1885). Among his publications are: *A Text-Book of Animal Physiology, etc.* (1889); *A Text-Book of Comparative Physiology* (1890); *How to Keep a Dog in the City* (1891); *The Dog in Health and Disease* (1892); *The Nature and Development of Animal Intelligence* (1898); *Voice Production in Singing and Speaking on Scientific Principles* (1906).

MILLS COLLEGE. A college for women, with a campus of 150 acres, in the suburbs of Oakland, Cal. It was founded as a seminary in 1865 and chartered as a college in 1885. In May, 1911, the seminary department was discontinued. Its entrance requirements are those of any standard college, and the degrees granted are A.B., B.L., and B.S. In addition to the regular departments of liberal culture it offers special opportunity for work in home economics, physical education, music, and fine arts. In 1914-15 the students numbered 137 and the faculty 32. The endowment of the college is \$500,000 and the value of the property \$500,000. The president in 1915 was Luella C. Carson, LL.D.

MILL SPRINGS, BATTLE OF. A battle fought at Mill Springs, Ky., about 10 miles west of Somerset, on Jan. 18, 1862, between a Federal force of about 4000 men under Gen. George H. Thomas and an approximately equal Confederate force under Gen. George B. Crittenden. The Confederates attacked with great energy, but were finally driven in some confusion from the field. The engagement is also sometimes called the battle of Fishing Creek and the battle of Logan's Crossroads. On the battleground a national cemetery was subsequently established, where 718 soldiers lie buried, 352 known and 366 unknown.

MILLSTONE. A wheel or circular mass of rock used in grinding wheat and other grains. For good millstones the rock must be tough, hard, and possess a cellular structure so as to maintain a rough grinding surface. Several varieties of rocks have been found to possess these qualities in a greater or less degree and have been extensively employed for millstones. In the United States the rock most commonly used is a coarse granular sandstone, which is obtained in Ulster Co., N. Y., in Lancaster Co., Pa., and in Montgomery Co., Va. The celebrated French buhrstones consist of a cellular chert occurring in the Tertiary of the Paris basin. The German millstones are largely quar-

ried from a sheet of basaltic lava found near Cologne. The foreign stone is imported into the United States in small pieces and is then built up into wheels, while the domestic stone is quarried and dressed to form a solid wheel. The introduction of the roller process for the manufacture of flour has curtailed the use of millstones to a great extent. In 1913 the production of millstones in the United States was valued at \$56,163. See ABRASIVES.

MILLSTONE GRIT. A hard siliceous conglomerate with quartz pebbles. Its geological position is at the base of the Pennsylvanian (Coal Measures) series of the Carboniferous system. The beds along the Appalachian Range in Pennsylvania are very coarse and are over 1200 feet thick. The rock here is a light-colored siliceous conglomerate known as the Pottsville Conglomerate, interstratified with some sandstone and thin beds of carbonaceous shells. The formation is represented also in New York and as far south as Alabama. Thin beds of coal are found in it in Pennsylvania, and in the southern Appalachians the coal beds are very important. See CARBONIFEROUS SYSTEM.

MILLVALE. A borough in Allegheny Co., Pa., on the Allegheny River, opposite Pittsburgh, with which it is connected by bridge, and on the Pennsylvania and the Baltimore and Ohio railroads (Map: Pittsburgh, F 2). It has iron manufactures, saw works, stone works, lumber mills, breweries, etc. The government is vested in a burgeess, elected every three years, and a borough council. The water works and electric-light plant are owned by the municipality. Pop., 1900, 6736; 1910, 7861.

MILL VALLEY. A town in Marin Co., Cal., 12 miles north of San Francisco, on the Northwestern Pacific and the Muir Woods and Mt. Tamalpais Scenic railroads (Map: California, C 5). It is situated in a region of remarkable scenic beauty and adapted to fruit growing. Mill Valley owns its water works. Pop., 1910, 2551.

MILLVILLE. A city in Cumberland Co., N. J., 40 miles south of Philadelphia, on the Maurice River, at the head of deep-water navigation, and on the Pennsylvania Railroad (Map: New Jersey, B 5). It has city and high-school libraries, a fine high-school building, a hospital, and a large public park at Union Lake, a beautiful sheet of water 3 miles long and 1½ in width. Millville is essentially a manufacturing centre, having extensive glass factories, iron foundries, cotton mills, wrapper and shirt-waist factories, and bleach and dye works. The city has adopted the commission form of government. Millville was incorporated as a town in 1801 and was chartered as a city in 1866. Pop., 1900, 10,583; 1910, 12,451; 1914 (U. S. est.), 13,246; 1920, 14,691.

MILMAN, HENRY HART (1791-1868). An English poet and ecclesiastical historian. He was the youngest son of Sir Francis Milman, physician to George III, and was born in London, Feb. 10, 1791. He was educated at Eton and afterward at Brasenose College, Oxford, where he obtained the Newdigate prize with an English poem on the Apollo Belvedere in 1812 and graduated B.A. in 1814. He published *Fazio, a Tragedy*, which was successfully brought upon the stage at Covent Garden in 1815; took orders in 1817, and in 1818 was appointed vicar of St. Mary's, Reading. In 1818 appeared his *Samor, Lord of the Bright City, an Heroic*

Poem, which was followed in 1829 by the *Fall of Jerusalem*, a dramatic poem with some fine sacred lyrics interspersed. In 1821 Milman was chosen professor of poetry at Oxford and held the position for 10 years. He published three other dramatic poems, *The Martyr of Antioch* and *Belshazzar*, both in 1882, and *Anne Boleyn* in 1826. His Bampton lectures on *The Character and Conduct of the Apostles Considered as an Evidence of Christianity* appeared in 1827 and his *History of the Jews* (3 vols.) in 1830. The last of these works did not bear the author's name. Its weak point was a want of adequate learning, especially in the department of biblical criticism, but its fresh, natural treatment of biblical history was a novelty and was severely attacked as heresy. A new edition, greatly improved and more critical, was published in 1863, and another, with further improvements, in 1867. He became a canon of Westminster and rector of St. Margaret's, Westminster, London, in 1835, and the same year he published certain translations of Sanskrit epic poetry. In 1840 appeared a collected edition of his *Poetical Works*, containing some other pieces besides those already mentioned. The same year witnessed the publication of his *History of Christianity from the Birth of Christ to the Abolition of Paganism in the Roman Empire* (3 vols.). In 1849 he was made dean of St. Paul's and discharged the duties of the office in such a manner as to win the title of "the Great Dean." In 1854-56 he published his masterpiece, *History of Latin Christianity, Including that of the Popes to the Pontificate of Nicholas V* (6 vols.), a work whose candid, sympathetic scholarship made an era in the study of ecclesiastical history in England. Milman edited Gibbon (1838) and an edition of Horace (1849), and published translations of the *Agamemnon* and *Bacchæ* (1865). He contributed extensively to the *Quarterly Review*. He died in Sunninghill, near Ascot, Sept. 24, 1868. A posthumous work contains his *Annals of St. Paul's Cathedral* (1868) and another *Essays on St. Paul, Savonarola, Erasmus, etc.* (1870). His historical works were republished in 15 volumes (1866-67). Consult his biography by A. Milman (London, 1900).

MILMORE, MARTIN (1844-83). An American sculptor. He was born at Sligo, Ireland, and in 1851 was taken to Boston. His first instruction was in wood carving, but in 1860 he began his studies in sculpture with Thomas Ball in Boston. His first work to receive notice was his ideal alto-relievo "Phosphor" (1863). In the same year he executed the statuette "Devotion" and later an ideal child statue and cabinet busts of Longfellow and Charles Sumner. In 1864 he was commissioned to execute statues of Ceres, Flora, and Pomona for Boston Horticultural Hall (Tremont Street). One of his most effective pieces is his soldiers' monument for Forest Hills Cemetery, Roxbury (1867), which ranks high among American works of art for conception and execution. The Soldiers' and Sailors' Monument on Boston Common, unveiled in 1874, is his greatest and most elaborate work and gives proof of an unusual sense of the monumental. While preparing designs for this work he resided at Rome, where he made busts of Pope Pius IX, Wendell Phillips, and Ralph Waldo Emerson. He died in Roxbury, Mass. Among other works are his life-size bust of Charles Sumner, Metropolitan Museum, New

York City; a statue of General Thayer, West Point, N. Y.; busts of General Grant, Lincoln, Daniel Webster, and others; war monuments at Keene, N. H., Erie, Pa., and Charlestown and Fitchburg, Mass. With his brother he executed the great granite Sphinx in Mount Auburn Cemetery, Cambridge, Mass. It was in commemoration of Milmore that Daniel Chester French modeled his celebrated bronze relief "Death and the Young Sculptor."

MILNE, mīln, JOHN (1850-1913). An English mining engineer and seismologist, born in Liverpool. He was educated at King's College and the Royal School of Mines in London and subsequently went to Newfoundland and Labrador, where he worked as a mining engineer. Later he was the geologist of Dr. Beke's expedition into northwestern Arabia, and was then for 20 years in the service of the Japanese government. During that period he established the seismic survey of Japan, which comprises more than 900 stations and which may be said to have inaugurated the systematic study of earthquake phenomena. In the course of his investigations he traveled over a great part of the world, visiting the United States, Russia, Siberia, Mongolia, Korea, China, the Kuriles, the Philippines, Borneo, and Australasia, and finally devoted himself to the establishment of a seismic survey of the world. He invented seismographs and instruments to record vibrations on railways, and published important works on seismology and geology, including *Earthquakes and Other Earth Movements* (1883; 6th ed., 1913); *Seismology* (1888); *The Miner's Handbook* (1894; 3d ed., 1902); *Crystallography*.

MILNE-EDWARDS, mīln-éd'wardz, Fr. pron. mel'ná'dwár', ALPHONSE (1835-1900). A French zoölogist, son of Henri Milne-Edwards, born in Paris. Though he took the degree of M.D. in 1860 he devoted his life to the study of zoölogy and, after holding various minor positions, was appointed professor of zoölogy in the Museum of Natural History, Paris, in 1876, becoming director in 1892. His earlier publications were in physiological medicine, but the greater part of his work was done in zoölogy, paleontology, and deep-sea exploration. His work on fossil Crustacea appeared in 1865; an extensive and valuable treatise on the fossil birds of France was published in 1866-72. He also described the extinct birds of the Mascarene Islands and of Madagascar. He worked long and patiently on the Crustacea, preparing elaborate reports on the deep-sea forms. His publications include: *Histoire des crustacés podophthalmes fossiles* (1865); *Recherches anatomiques et paléontologiques pour servir à l'histoire des oiseaux fossiles de la France* (2 vols., 1867-72); *Expéditions scientifiques du travailleur et du talisman* (1888).

MILNE-EDWARDS, HENRI (1800-85). A French naturalist, born at Bruges. His father was an Englishman. He studied medicine, but after taking his degree in 1823 turned to the study of zoölogy and began his scientific career by publishing, in 1828, his *Recherches anatomiques sur les crustacés*. In 1841 he was appointed professor of entomology at the Museum of Natural History, Paris. In 1862 he succeeded Geoffrey St. Hilaire in the chair of zoölogy and in 1864 became director. From 1837 on he edited the zoölogical portion of the *Annales des sciences naturelles* and contributed extensively to this journal. He was the first to describe the

important biological principle of the physiological division of labor. His most important works besides the *Recherches* above mentioned were: *Éléments de zoölogie ou leçons sur l'anatomie, la physiologie, la classification, etc., des animaux* (1834-35; republished as a new edition with the title *Cours élémentaire de zoölogie*, 1851); a completion and revision of Lamarck's *L'Histoire naturelle des animaux sans vertèbres* (1836-45), with Deshayes; *Leçons sur la physiologie et l'anatomie comparées de l'homme et des animaux* (1855-84).

MILNER, ALFRED, first VISCOUNT (1834-1925). An English colonial Governor, born at Bonn, Germany, March 23, 1834. He studied at Tübingen, at King's College, London, and at Balliol College, Oxford, studied law, and from 1882 to 1885 devoted himself to journalism, serving under John Morley and W. T. Stead. His service as private secretary to G. J. (afterward Lord) Goschen, Chancellor of the Exchequer (1887-89), began his public career. He proved an able Undersecretary for Finance in Egypt (1889-92), publishing his observations as *England in Egypt* (1892; 12th ed., 1915), and was chairman of the Board of Inland Revenue in 1892-97. In 1897 Milner was appointed High Commissioner for South Africa and Governor of the Cape of Good Hope. He held the former post through the difficult period preceding and succeeding the South African War; was created Viscount in 1902, and in 1901 was appointed Governor of the Transvaal and Orange River Colonies. He resigned as High Commissioner and Governor in March, 1905, and returned to England. Regarded by many as coauthor with Cecil Rhodes and Mr. Chamberlain of the South African War, he was subjected to much criticism in Liberal circles, especially after the fall of the Unionist ministry in December, 1905. In March, 1906, the House of Commons expressed in an indirect way its disapproval of his action in permitting the flogging of a Chinese coolie in the Transvaal. In reply the House of Lords, by an overwhelming vote, placed on record its high appreciation of Lord Milner's services, and in August he was presented with an address of the same nature signed by more than 370,000 names. He published *The Nation and the Empire* (1913). Consult: E. B. Iwan-Müller, *Lord Milner and South Africa* (London, 1902); W. B. Worsfold, *Lord Milner's Work in South Africa* (ib., 1906); id., *The Reconstruction of the New Colonies under Lord Milner* (2 vols., ib., 1913).

MILNER, JOHN (1752-1826). An English Roman Catholic scholar, born in London. He was ordained priest in 1777; settled at Winchester in 1779; became titular Bishop of Castabala in 1803, and was made Apostolic Vicar of the Midland District in England. In 1804 he moved to Wolverhampton and entered into the agitation which finally led to the removal of the right of veto on appointment of Roman Catholic bishops as part of Peel's Catholic Relief Act passed in 1829. His firmness and courage in the controversy won him the sobriquet "the English Athanasius." He wrote: *Antiquities of Winchester* (2 vols., 1798-1801; 3d ed., with memoir by Husenbeth, 1839); *Treatise on the Ecclesiastical Architecture of England during the Middle Ages* (1811; 3d ed., 1835); *The End of Religious Controversy* (1818). Consult: F. C. Husenbeth, *Life of John Milner* (Dublin, 1862); Ward, *Daunt of the Catholic Revival in England, 1781-1803* (2 vols., ib., 1909).

MILNER, JOSEPH (1744-97). An English ecclesiastical historian. He was born at Leeds in Yorkshire. He studied at Catharine Hall, Cambridge, where he took the degree of B.A. in 1766, and afterward became head master of the grammar school at Hull. In 1768 he was appointed lecturer at Holy Trinity or High Church, Hull, and later became also vicar at North Ferriby, near Hull. Milner's principal work is his *History of the Church of Christ*, of which he lived to complete three volumes, reaching to the thirteenth century (1794-97); vols. iv and v (1803-09) were edited from his manuscripts by his brother, Dr. Isaac Milner, dean of Carlisle, who also published a complete edition of his brother's works in eight volumes (1810). The principles on which the *History of the Church of Christ* is written are of the narrowest kind of evangelicalism. An improved edition by Grant-ham appeared in 1847. A life of Milner by his brother Isaac is prefixed to the first volume of Milner's *Practical Sermons* (London, 1804-23).

MILNER-GIBSON, THOMAS. See GIBSON, THOMAS MILNER.

MILNES, miln'z, RICHARD MONCKTON, BARON HOUGHTON (1809-85). An English poet and politician, son of Robert Pemberton Milnes, of Fryston Hall, near Wakefield, Yorkshire, born in London, June 19, 1809. He was educated at Trinity College, Cambridge, where he was a member of the famous society called the Apostles, which included Hallam and Tennyson. Soon after receiving the degree of M.A. (1831) he traveled in Germany and Italy and visited Greece. He returned to London in 1835. In 1837 he entered Parliament for Pontefract, which he continued to represent till 1863, when he was raised to the peerage as Baron Houghton. In politics he was at first a Conservative, but on Peel's conversion to free trade he became an Independent Liberal. He was an advocate of public education and religious equality; labored for copyright laws and the establishment of reformatories for juvenile offenders; and took a decided stand on the side of Italy against Austria. A friend of literary men, he secured a pension for Tennyson, helped Hood, and was one of the first to recognize the merits of Swinburne. In 1842-43 he visited the East and in 1875 Canada and the United States. He died at Vichy, Aug. 11, 1885. He is more memorable as a man of influence in the worlds of society and letters than as an original writer, though the delicacy and refinement of his meditative poetry has a narrow appeal. Among Lord Houghton's works are: *Memorials of a Tour in Some Parts of Greece, Chiefly Poetical* (1834); *Poems of Many Years* (1838); *Poems Legendary and Historical* (1844); *Palm Leaves* (1844). He edited *The Life, Letters, and Literary Remains of Keats* (1848). Consult his interesting *Monographs, Personal and Social* (London, 1873); *Collected Poetical Works* (ib., 1876); and the character of Vavasour in Disraeli's *Tancred*; T. W. Reid, *Life, Letters, and Friendship of R. M. Milnes* (London, 1890).

MILO. A town in Piscataquis Co., Me., 34 miles north-northwest of Bangor, on the Bangor and Aroostook Railroad (Map: Maine, D 3). The town is engaged largely in farming, and there are also manufactories of spools, long lumber, and the repair shops of the Bangor and Aroostook Railroad. Pop., 1900, 1150; 1910, 2556.

MILO. See MELOS.

MILO, or MILON (Lat., from Gk. Μίλων, *Mílon*) of Croton, in Magna Græcia. A Greek athlete famous for his great strength, who lived, according to Herodotus, about 520 B.C. He won the prize as wrestler in six Olympian, seven Pythian, ten Isthmian, and nine Nemean games. Among other displays of his strength he is said to have on one occasion carried a live ox upon his shoulders through the stadium of Olympia and afterward to have eaten the whole of it in one day; and on another to have upheld the pillars of a house in which Pythagoras and his scholars were assembled, so as to give them time to make their escape when the house was falling. He lost his life through too great confidence in his own strength, when he was getting old, in attempting to rend a tree which woodcutters had partly split with a wedge; as the result of his first effort the wedge fell out, but when he relaxed his muscles for a fresh effort the tree closed upon his hands and held him fast until he was devoured by wolves.

MILO, TITUS ANNIUS PAPIANUS (95-48 B.C.). A Roman politician. He was born at Lanuvium and belonged to a distinguished family. Few details of his life are known till his election as tribune of the people in 57 B.C. He was then a partisan of Pompey and attempted to bring about the recall of Cicero from exile. This measure was bitterly opposed by Clodius, who, as tribune of the people, had been instrumental in passing the law condemning Cicero to exile. Milo attempted to have Clodius condemned as a violator of the public peace, but the proceedings were quashed. Both Milo and Clodius now hired a bodyguard of gladiators, and armed collisions between their retainers became almost everyday occurrences. About this time Milo married Sulla's daughter, Fausta, for her fortune. In 56 Clodius was elected curule ædile and accused Milo of being a violator of the public peace by keeping a force of armed retainers. Pompey conducted the defense of Milo, but no decision was ever reached. In 53 Milo offered himself as a candidate for the consulship. Clodius opposed the candidature of Milo, who was defended in the Senate by Cicero in a speech of which some fragments are still extant. On January 18 of the next year Milo was on his way to Lanuvium from Rome, accompanied by 300 persons, many of whom were women and children. Clodius, also with an armed company, met him near Bovillæ. Milo and Clodius passed each other without trouble; but some of Milo's followers picked a quarrel with the slaves of Clodius, who attempted to interpose and was stabbed in the shoulder by one of Milo's men. Clodius was taken to a tavern in Bovillæ, but was dragged out by the slaves of Milo and put to death. The corpse of Clodius was placed on the rostra of the Forum in Rome and a mob set fire to the Senate house. These acts of popular violence created a reaction in favor of Milo, who ventured to return to Rome. He was, however, tried for the murder of Clodius. Cicero defended him, but, intimidated by the violence of Clodius' partisans, failed to do justice to himself or to his client; Milo was condemned to exile and went to Marseilles. Later Cicero rewrote his *Oratio pro Milone*; the latter speech, still extant, has been justly admired both in ancient and in modern times. For a good account of the speech, of the death of Clodius, and the trial of Milo, consult R. W. Husband, "The Prosecution of Milo: A Case of

Homicide, with a Plea of Self-Defense," in *The Classical Weekly*, vol. viii, pp. 146-150, 156-159 (New York, 1915). In his absence he was tried and condemned on charges of violence, of bribery, and conspiracy.

In 48 he went back to Italy, without permission, to join Marcus Caelius, an expelled Senator, who was attempting to excite a rebellion in south Italy.

He was killed before a fort near Thurii. See **CLODIUS PULCHER**.

MILO, VENUS DL. See **MELOS**; **VENUS OF MILO**.

MILORADOVITCH, mé'ló-rá'dó-vich, MIKHAIL ANDREIEVITCH, COUNT (1771-1825). A Russian general, born in St. Petersburg. After active service in the war with Turkey and in that with Poland he distinguished himself under Suvarov in the campaign of the Austro-Russian army against the French in Italy (1799) and made the famous passage of the Alps by way of the St. Gotthard Pass into Switzerland. In 1805 he was a division commander at Austerlitz and in 1812 he fought at Borodino. In 1813 he played a prominent part at Lützen. He was made Governor of St. Petersburg in 1819, but six years afterward, as he strove to quell the Decembrist rising, he was shot dead.

MILOSH, mé'lósh, OBRENOVITCH (1780-1860). A prince of Serbia, born in Dobrinia. He was the son of a peasant and spent his youth and early manhood as a swineherd in the service of his rich half brother Milan, who was one of the leaders in the revolt of 1804. Milosh was his lieutenant and his successor (1810), took his patronymic in place of his own, Todorovitch, and became a leader in the opposition against Kara George. After the latter fled into Austria Milosh stood his ground against the Turks for a time, then surrendered, and was made commandant or "knez" of Rudnik (1813). In 1815, as a result of brave fighting and clever diplomacy, he practically made Serbia independent. Two years afterward, having killed Kara George, he was named hereditary and supreme Prince of Serbia, a title conferred in 1827 by the National Assembly and recognized by the Porte in 1830. Several revolts came to nothing, but in 1839 he was forced to abdicate in favor of his son, Milan. The next nine years he spent in Vienna and later he settled on his estates in Serbia. In 1858 he was recalled to power by the National Assembly and recognized by the Porte in 1859. He was a man of no education, energetic, headstrong, and rather cruel; but he gave Serbia a place in European politics. For this he is known as the "father of his country." He was succeeded by his son Michael Obrenovitch III.

MILREIS, mil'rás, or **MILREA**, mil'rá (Portug., from *mil*, thousand + *reis*, pl. of *real*, small coin). Portuguese and Brazilian coins and money of account, containing 1000 *reis*. The Portuguese gold milreis is equivalent to the escudo, the monetary unit of Portugal, of which the value in United States currency is \$1.08. The Brazilian milreis, the monetary unit of Brazil, is a gold coin equal to 54.6 cents value in United States currency, but is not in general circulation. There are silver coins and paper currency of the same name, which fluctuate in value, the paper milreis being quoted by the United States Treasury Department in October, 1914, at about 25 cents United States currency.

MIL'ROY, ROBERT HUSTON (1816-90). An

American soldier, born in Washington Co., Ind. He graduated at Norwich University, Northfield, Vt., in 1843, and took part in the Mexican War as captain in an Indiana volunteer regiment. While studying law he served as a member of the Indiana Constitutional Convention in 1849-50 and in 1851 was made judge of the eighth judicial circuit of Indiana. At the outbreak of the Civil War he was made captain, in 1861 was made colonel of volunteers, and finally brigadier general in 1862. In the same year he was promoted to be a major general of volunteers after his service in West Virginia under Generals McClellan and Rosecrans. At Winchester, Va., he opposed for three days a large part of Lee's army, then attempted the invasion of Pennsylvania, and lost heavily. Though he claimed that this detention of Lee was of great advantage to General Meade, enabling him to fight at Gettysburg instead of farther north, an investigation was ordered into his conduct. The charges, however, were dismissed; but he resigned from the army. In 1868 he was trustee of the Wabash and Erie Canal, was superintendent of Indian affairs in Washington Territory from 1868 to 1874, was Indian agent from 1875 to 1885, was reappointed in the latter year, but soon lost his position by the accession to power of the opposite political party.

MILTIADES (Lat., from Gk. Μιλτιάδης).

1. A prominent Athenian of the sixth century B.C., son of Cypselus, political adversary of Pisistratus. Herodotus states (vi, 36-37) that, at the request of the Dolonians, as an aid to them against their foes, Miltiades conducted a colony to the Thracian Chersonese. Modern scholars, however, have held rather that Pisistratus, seeking trade in Thrace and along the Hellespont, sent out the colony and put Miltiades in charge to remove a rival from Athens. 2. A famous Athenian general, son of Cimon (q.v.). He became "tyrant" of the Chersonesus after his brother Stesagoras, and accompanied Darius Hystaspis in his expedition against the Scythians, about 508 B.C. (See **DARIUS I.**) He was one of those who were left by Darius in charge of the bridge over the Danube, and, when Darius failed to appear at the expected time, he advised that the bridge be destroyed and Darius left to his fate. This story, told by Herodotus, vi, 40, modern scholars doubt. Consult W. W. How and J. Wells on Herodotus, l.c. (Oxford, 1912). Afterward he took Lemnos from the Persians, but, when the Persian fleet came near the Chersonesus, fled to Athens. Being chosen one of the 10 generals of the year 490 B.C., he defeated the Persians in that year in the great battle of Marathon (q.v.). Later he was entrusted by the Athenians with a fleet of 70 ships, with which he proceeded against Paros for the purpose of avenging a private grudge. The expedition having failed, he was, on his return to Athens, condemned to pay a fine of 50 talents. Being unable to do this, he was thrown into prison, where he died of an injury received at Paros. The biography of this Miltiades by Cornelius Nepos (q.v.) is extant.

MILTIADES, SAINT, less correctly called **MELCHIADES**. Pope 311-314. He was born in Africa and his pontificate covers the eventful period of Constantine's conversion. Under him a synod was held in Rome in 313 and a decision was rendered against the Donatists (q.v.). His day is December 10.

MILTITZ, KARL VON (c.1480–1529). A German ecclesiastic of the Roman Catholic church, the son of a Saxon noble. He was canon at Mainz, Treves, and Meissen before he became papal chamberlain and notary in 1515. Three years afterward he was sent by Pope Leo X to Saxony on the mission to confer with Martin Luther and his protector, the Elector Frederick the Wise, in the matter of indulgences. An able and politic advocate for a compromise, Miltitz so far succeeded that Luther promised future submission, if not recantation; but though later meetings took place between the two at Liebenwerda and Lichtenberg, the hope of reconciliation was definitely abandoned on the arrival of a denunciatory papal bull. Miltitz was charged also with an investigation into the conduct of Tetzl, whom he condemned. Consult his biography by Creutzberg (Freiburg, 1907).

MILTON. A town and the capital of Halton County, Ontario, Canada, on the Canadian Pacific and Grand Trunk railways, about 30 miles southwest (direct) of Toronto (Map: Ontario, E 6). It has manufactories of lumber, flour, wire nails, cream, pressed brick, boots and shoes, crushed stone and lime, wood screws and rivets, carpets, nickel and silver plating, and electric motors. The town possesses two parks and owns its electric-lighting and water works. Pop., 1911, 1654.

MILTON. A town, including the villages of East Milton, Lower Mills, and Mattapan, in Norfolk Co., Mass., 7 miles south of Boston, on the Neponset River and on the New York, New Haven, and Hartford Railroad (Map: Massachusetts, E 3). It is an attractive residential suburb of Boston and has a public library, Milton Academy, and other institutions. In proportion to its size it is a very wealthy town, its valuation in 1914 being \$31,602,839. The crest of the highest hill (635 feet) of the Blue Hills is the site of a meteorological observatory, conducted by Harvard University. A fine view is afforded. The town has granite quarries and chocolate and cracker factories. The government is administered by town meetings. There are municipal water works. Pop., 1900, 6578; 1910, 7924. Settled in 1637, Milton was a part of Dorchester until, in 1662, it was incorporated as a separate township. It was the home for many years of Jonathan Belcher, a Colonial Governor of both Massachusetts and New Jersey, and of Thomas Hutchinson, the historian and Colonial Governor of Massachusetts. It is also the site of the famous Suffolk Resolves house. Consult Teele (editor), *History of Milton, Mass.* (Milton, 1887).

MILTON. A borough in Northumberland Co., Pa., 50 miles north of Harrisburg, on the Susquehanna River, on the Pennsylvania Canal, and on the Pennsylvania and the Philadelphia and Reading railroads (Map: Pennsylvania, H 4). Its extensive manufacturing plants include car and woodworking machinery shops, rolling, flour, knitting, planing, and saw mills; washer, nut, and bolt works; and furniture, shoe, couch, nail, fly net, bamboo novelty, and paper-box factories. The borough has a public park with picturesque scenery; and a fine bridge spans the Susquehanna at this point. Settled in 1770, Milton was incorporated first in 1817. It is governed, under a revised charter of 1890, by a chief burgess, elected every four years, and a unicameral council. Pop., 1900, 6175; 1910, 460.

MILTON, JOHN (1608–74). An English poet. He was born in Bread Street, London, Dec. 9, 1608. His father, also named John Milton, belonged to a Roman Catholic family of yeomen living in Oxfordshire. The elder John Milton was converted to Protestantism while a student at Oxford, and as a result was promptly disinherited by his father, Richard Milton. The poet's father settled in London, where he prospered as a scrivener. The younger John Milton received instruction from his father in music, was taught by a private tutor, and was sent to St. Paul's School (about 1620), where he learned Latin, Greek, French, Italian, and some Hebrew, and read English literature. Spenser's *Faerie Queene* and Sylvester's translation of Du Bartas, which came into his hands at this time, exerted much influence on the formation of his style. In February, 1625, he proceeded to Christ's College, Cambridge. He was of less than the middle height, yet well made, with light brown or auburn hair. In bearing he was courteous and stately, though sometimes sarcastic. Owing to a quarrel with his first tutor he was rusticated for a short time in 1626, but he returned and completed the course, graduating B.A. in 1629 and M.A. in 1632. From childhood Milton had been destined for the Church, but the policy of Laud led him first to postpone taking orders and then to abandon all thought of it. He retired to his father's estate at Horton, Buckinghamshire, where he passed nearly six years (1632–38) in reading the classics and writing at intervals his choicest poems. Believing that he had it in him to write something that would live, he set out for Italy in April, 1638, wishing to fit himself still more for his future work. Probably at Bologna, which he visited in 1639, Milton wrote in excellent Italian five sonnets and a canzone wherein he expresses love for a beautiful lady of Bologna. For some time he stayed in Florence, where he visited in prison the blind Galileo. Thence he went on to Rome and Naples. As he was about to pass over to Sicily and from there to Greece, news reached him of "the civil commotions in England." He turned homeward, reaching England towards the end of July, 1639. He took a house in Aldersgate Street, London, where he received as pupils two nephews, children of an elder sister, and occupied his leisure with plans for future poems. From these pursuits he was drawn into ecclesiastical controversies, writing pamphlet after pamphlet. In June, 1643, he married, after a brief courtship, Mary Powell, then only 17 years old, the daughter of an Oxfordshire squire and Royalist. After a month the bride returned to her father's house. In the summer of 1645 they were reconciled, and he moved to the Barbican, a more commodious house for the increasing number of his pupils. His wife died in 1652, after bearing four children, of whom the one son died in infancy. A fortnight after the execution of Charles I (Jan. 30, 1649) Milton issued a memorable defense of the deed, and this led to other pamphlets which gave him European fame as a controversialist. On the establishment of the Commonwealth Milton was appointed Latin secretary to the Council of State (March 15, 1649). For this office, involving the duty of turning into Latin all foreign dispatches, he was eminently fitted. In 1652 he lost his eyesight, already long impaired, but with the aid of assistants—one of whom was Andrew Marvell—he performed the duties of his

post till the abdication of Richard Cromwell (1659). In the meantime (November, 1656) he had married a Catharine Woodcock, who died in February, 1658. She was honored by one of Milton's most beautiful sonnets (xxiii). The Restoration put an end to his active career. In 1661 he settled in Jewin Street, Aldersgate, from which he removed about two years later to a house in Artillery Walk, Bunhill Fields, his last residence. Here he fulfilled the literary task he had long ago planned and since begun. In 1663 he married a third wife, 30 years his junior, named Elizabeth Minshull. His relations with his daughters were most unhappy. Brought up in ignorance, they revolted from the service that he demanded of them—reading to him Latin, Greek, and Hebrew, which of course they could not understand. Towards the end Milton stood aloof from religious sects and services. He died Nov. 8, 1674, and was buried in St. Giles's, Cripplegate.

Milton's literary career is clearly divided by the outbreak of the Civil War and by the Restoration into three periods: (1) 1626-40; (2) 1640-60; (3) 1660-74.

First Period. Milton began writing English and Latin verse while a schoolboy. The earliest extant specimens of these exercises are paraphrases of the 114th and 136th Psalms, composed at the age of 15, and some Latin verses. To his Cambridge period belong a group of Latin poems (1626-28); "On the Death of a Fair Infant" (1626); "At a Vacation Exercise" (1628); "Hymn on the Morning of Christ's Nativity" (1629); the fragment "The Passion" and "Song on May Morning" (both probably 1630); "On Shakespeare" (1630); and sonnets "To the Nightingale" (probably 1630) and "On Arriving at the Age of Twenty-three" (1631). The Latin verses are undoubtedly the best ever written by an Englishman, and the best of the English poems display high poetical genius. While at Horton, Milton composed four perfect poems: the two descriptive lyrics, "L'Allegro" and "Il Penseroso" (probably written in 1632); "Comus," a masque performed at Ludlow Castle on Michaelmas night, 1634, in honor of Lord Bridgewater's appointment to the wardenship of the Welsh marches; and "Lycidas," a pastoral elegy in memory of his college friend Edward King, drowned on his passage to Ireland (Aug. 10, 1637). Of these poems, which by themselves would give Milton a high place in English literature, only a few had been published. The lines on Shakespeare appeared in the second folio of the dramatist's works (1632); Henry Lawes, who composed the music for "Comus," published the masque anonymously (London, 1637), and "Lycidas" formed one in a collection of memorial poems (Cambridge, 1638). To this period belong five sonnets and a canzone in Italian and Milton's two finest Latin poems: "Mansus" (1638), addressed to the Marquis of Manso, the friend of Tasso, who in his old age hospitably received Milton at Naples; and "Epitaphium Damonis," an elegy on the death of his college friend Charles Diodati.

Second Period. For full 18 years Milton was distracted from poetry by the revolutions in church and state, and doubtless also by his own domestic perplexities. The separation from his wife led to pamphlets on divorce, of which the most important are "The Doctrine and Discipline of Divorce" (Aug. 1, 1643) and "The Tetrachordon" (1645). Against episcopacy he

launched, in 1641-42, five tracts, of which the best known is "The Reason of Church Government Against Prelaty." In 1644 appeared the valuable letter "Of Education" and a noble plea for the freedom of the press under the title "Areopagitica." The execution of Charles I and the establishment of the Commonwealth were defended against continental criticism in "The Tenure of Kings and Magistrates" (1649), "Eikonoklastes" (1649), "Pro Populo Anglicano Defensio" (1651), and sequels. These tracts, vehement and often scurrilous in style, contain autobiographical passages of interest. Throughout this period Milton wrote almost no verse. He composed, however, at intervals his magnificent sonnets, as "On his Blindness," "To Fairfax," "To Cromwell," and "The Massacre in Piedmont"; and the first edition of his collected poems was published, probably early in January, 1646, though dated 1645. Besides this he wrote some Greek and Latin verse and made a few translations. In 1648 there appeared a romance in Latin, in mixed prose and verse, and entitled "Nova Solyma," which was translated (New York, 1902) by the Rev. Walter Begley, and by him attributed to John Milton—an attribution which has not been generally sanctioned, however, by scholars.

Third Period. The great epic that Milton now composed is the spiritual summary of his life of lost ideals. As early as his return from Italy, he had meditated the production of some great poem. By 1642 his mind was turning towards a play on the loss of paradise. When he resumed the subject in 1658, it took the form of an epic. "Paradise Lost," in 10 books, completed by 1665, perhaps even by 1663, was first published in 1667. After several reprints with slight changes, it was enlarged to 12 books (1674). For this poem, of which 1300 copies were sold in 18 months, Milton received from his publisher £5 down, and an agreement to pay the poet £15 more in three installments on condition of the sale of a certain number of copies. At the suggestion of Thomas Ellwood, a Quaker friend of the poet, Milton wrote "Paradise Regained," which was published with "Samson Agonistes," a lyrical drama, in 1671.

Once Milton was known mainly as the author of "Paradise Lost." Since the romantic revival, the minor poems, touchstones of poetic taste, have taken a secure place beside this epic. The glow and romance of the imaginative state in which the early lyrics were conceived certainly departed from Milton during the civil conflict. But as years went on his imagination became invested with sublimity. Had "Paradise Lost" been written in 1642, it would have been a perfect mystery play, as "Comus" is a perfect masque. Delayed 20-odd years it became a sonorous epic, which, though barren in places, abounds in the noblest English poetry.

Bibliography. For his biography, consult: Edward Phillips's (Milton's nephew) memoir in his *Letters of State* (London, 1694); David Masson, *Life of John Milton, Narrated in Connection with the Political, Ecclesiastical, and Literary History of his Time* (new and rev. ed., 7 vols., London, 1877-96), exhaustive and authoritative; Mark Pattison, in the "English Men of Letters Series" (New York, 1880); Richard Garnett, in the "Great Writers Series" (London, 1890); Masterman and Mullinger, *The Age of Milton* (ib., 1897); "The Earliest Life of Milton," written by a contemporary of the poet and

JOHN MILTON
FROM AN ENGRAVING BY GEORGE VERTUE

reprinted in *Colorado College Studies* (No. x, Colorado Springs, 1903). For works, consult: *The Poetical Works of Mr. John Milton* (London, 1695), the first complete edition of his poetry; *Poetical Works*, edited by H. J. Todd (6 vols., ib., 1801), by J. Mitford (Aldine edition, 3 vols., ib., 1832); *Prose Works*, edited by St. John, Bohn's Library (5 vols., ib., 1848-53); *Poetical Works*, edited by Keightley (2 vols., ib., 1859); *Poetical Works*, edited by Masson (Cabinet edition, with memoir and excellent and complete editorial equipment, 3 vols., ib., 1890); John Bradshaw (comp.), *Concordance to the Poetical Works of John Milton* (ib., 1894); *Facsimile of Milton's Minor Poems*, from manuscripts in Trinity College, Cambridge, edited by Wright (Cambridge, 1899); *Poetical Works after the Original Texts*, i.e., reprints, edited by Beeching (Oxford, 1900). For estimate, consult: essays by Dr. Johnson (London, 1779), T. B. Macaulay (ib., 1840), J. R. Lowell (ib., 1845); W. P. Trent, *A Short Study* (New York, 1899); Hiram Corson, *An Introduction to Works*, containing the prose autobiographical pieces (ib., 1899); the notable *Study*, by Sir Walter Raleigh (ib., 1900). The student will find of much value C. G. Osgood, *The Classical Mythology of Milton's English Poems* (New York, 1900), and L. E. Lockwood, *Lexicon to the Poetical Works of John Milton* (ib., 1902). A valuable study is that of Robert Bridges, *Milton's Prosody* (London, 1893). Concerning sources and other questions there is good matter in Marianna Woodhull, *The Epic of Paradise Lost* (New York, 1907). In 1908, on the tercentenary of Milton's birth, an exhibition of editions and portraits of Milton was held, and the *Catalogue* (London, 1908) of this exhibition is bibliographically and iconographically valuable. There is matter of interest in S. G. Spaeth, *Milton's Knowledge of Music* (New York, 1913); in J. M. Bailey, *Milton and Jakob Boehme* (Oxford, 1914); and in E. N. S. Thompson, *Essays on Milton* (New York, 1915).

MILTON COLLEGE. A coeducational institution for higher education, founded at Milton, Wis., under the auspices of the Seventh Day Baptists. The college was incorporated under its present name in 1867, and it succeeded Du Lac Academy, founded in 1844 and in 1848 renamed Milton Academy. There are on the campus four buildings devoted to educational purposes, the last of these being a gymnasium, also used as an auditorium, erected in 1911 at a cost of \$22,000. The college includes collegiate and academic departments and a school of music. In 1914-15 the total attendance in all departments was 145, with 14 members in the faculty. The value of the property owned by the college was \$200,000, the buildings and grounds being valued at \$65,000 and the equipment at \$12,000. There is an endowment of \$135,000, and the annual income is about \$12,000. In the library are about 9500 volumes and 500 pamphlets. The president in 1915 was W. C. Daland, A.M., D.D.

MILUTIN, mil-yoo'tin, DMITRI ALEXEIEVITCH, COUNT (1816-1912). A Russian general and military reformer. He was born in Moscow, entered the army in his youth, and was appointed chief of staff in the Caucasus in 1856. In 1862, after submitting his programme for a reform of the Russian army, he was made Minister of War, a place he held till 1881. In 1898 he was made field marshal. Milutin wrote

on the campaign of 1839 in northern Daghestan and on Suvarov's campaign of 1799 against France—*A History of the War of 1799 between Russia and France in the Reign of Czar Paul I* (1853). The latter ranks very high among military annals.

MILUTIN, NIKOLAI (1818-72). A Russian statesman, brother of Count Dmitri. In Alexander II's reforms he took a prominent part, especially in the reorganization of credit, in the introduction of provincial institutions centering on the *mir*, in the emancipation of the serfs, and in agrarian commissions in Lithuania in 1863 and in Poland in 1864. He was Secretary of State for Poland from 1866 to 1868. He wrote on Russian military statistics. Consult Leroy-Beaulieu, *Un homme d'état russe* (Paris, 1884).

MIL/VIAN, or **MULVIAN BRIDGE.** An ancient bridge over the Tiber at Rome, built in 109 B.C. by Marcus Æmilius Scaurus, on the famous Flaminian Way (q.v.). At this bridge, in 63 B.C., Cicero caused the arrest of the ambassadors of the Allobroges, who were conspiring with Catiline, and Maxentius was drowned there after his defeat by Constantine in 312 A.D. On the foundations of the ancient bridge stands the modern Ponte Molle. Consult S. B. Platner, *The Topography and Monuments of Ancient Rome* (2d ed., New York, 1911).

MILWAUKEE, mil-wó'ké. The largest city in Wisconsin, a port of entry, and the county seat of Milwaukee County. It is situated in the eastern part of the State, on the west shore of Lake Michigan, 85 miles north of Chicago, and 82 miles east of Madison, the State capital (Map: Wisconsin, F 5). The city occupies an area of about 26 square miles, trisected by the Milwaukee River and its affluents, the Menominee and Kinnickinnic, all of which have been dredged and widened to permit passage into the heart of the city of large freight and passenger vessels. Much of the residence section of Milwaukee is upon a bluff rising 150 feet above Lake Michigan and 650 feet above sea level. Upon this bluff and ranging northerly and westerly from the business quarter are broad well-paved streets, characterized by shade trees and detached houses. The park and boulevard system, the graceful sweep of the bay with its prongs—North Point and South Point—projecting far into the lake, the city's proximity to well-known health and pleasure resorts, and its cluster of busy and beautiful suburbs all combine to make Milwaukee one of the most attractive of American cities. Among its suburbs are St. Francis, the seat of Pio Nino College and other Catholic institutions; West Allis, containing the State fair grounds and the immense machinery plant of the Allis-Chalmers Manufacturing Company; and Wauwatosa, the seat of a group of county institutions: almshouses, hospital, chronic insane asylum, hospital for the insane, and a children's home; here also is a national soldiers' home, occupying 400 acres of ground. A little further removed are the suburbs South Milwaukee and Cudahy, abounding in large manufacturing establishments. The park and boulevard system is a recent and rapid development. The city owns 940 acres of parks, under the control of commissioners, appointed by the mayor. The largest of these parks are Evergreen (180 acres), Washington (150 acres), Lake (125 acres), Jackson (80 acres), Mitchell (63 acres), Humboldt (46 acres), and Kosciusko (37 acres). All are beautifully laid out,

and most either include or are bordered by bodies of water. They are rendered more attractive by golf links, tennis courts, play grounds, a zoo (in Washington Park), and statues of distinguished men—Goethe, Schiller, Kosciusko, Robert Burns, Leif Ericson, Henry Bergh, and Solomon Juneau, the founder of Milwaukee. There is also a soldiers' monument on a slightly elevated situation on Grand Avenue. Forest Home cemetery abounds in monuments of taste and beauty. Store and residence buildings were formerly constructed for the most part of cream-colored bricks, from which Milwaukee became known as "The Cream City." Vitrified brick, however, is rapidly superseding this type of block, and new and ample structures arise in marble. The Wells, Pabst, Majestic, and First National Bank buildings are instances of the city's handsome business edifices. The Marshall and Ilsley Bank building, occupied in 1913, and the Northwestern Mutual Life Insurance Company building, completed in 1914, are particularly noteworthy—the former of Ionic architecture, and the latter a stately structure with Corinthian columns and pilasters. St. Paul's church (Protestant Episcopal), the Immanuel Presbyterian church, and the Jesuit church of the Gesu are also of great beauty. A Roman Catholic archbishopric and a Protestant Episcopal bishopric have sees in Milwaukee. The United States contributes to the architecture of Milwaukee by means of a large granite post-office building; the county of Milwaukee by a brown sandstone court and records building; and the city by its municipal house or city hall, situated on a triangular plat and surmounted by a commanding tower. Other prominent features are the public library and museum, containing 288,360 volumes, and among other rarities, the notable Nunnemacher collection of fire arms; and the art gallery, founded and endowed by Frederick Layton, and containing a choice collection of modern canvases, including *The Departure of the Mayflower*, by George H. Boughton, R.A. The public schools of Milwaukee are controlled by a board of school directors, 15 in number, elected by popular vote for a term of six years. Connected with the system are schools for the blind and deaf, vocational schools, and a fresh-air school. A fine State normal school is situated in the outskirts of the city. In addition to these there are a number of parochial schools, and Concordia College (Lutheran), established in 1881; Marquette University (Jesuit), founded in 1881; and Milwaukee-Downer College and Milwaukee-Downer Seminary, founded in 1849, both for women. Milwaukee's finest hospital is St. Mary's, with a new and splendidly equipped building, situated upon a slightly bluff of Lake Michigan's shore. In its immediate vicinity is a group of eleemosynary institutions, conspicuous among which are the Wisconsin Industrial School for Girls and the Milwaukee Protestant Home for the Aged. By the water of the lake, near the foot of these buildings, begins the Lake Shore Drive, which is to be a portion of the boulevard and park system, and which will surround practically the entire urban district. Pop., 1840, 1712; 1850, 20,061; 1860, 45,246; 1870, 71,440; 1880, 115,587; 1890, 204,468; 1900, 285,315; 1910, 373,857; 1914 (U. S. est.), 408,683; 1920, 457,147. In population Milwaukee ranks as the thirteenth city in the United States.

Its executive officer is a mayor, its legislative body a board of 37 aldermen, one chosen from

each of the 25 wards and 12 at large. A treasurer, a comptroller, an attorney, seven civil judges of limited jurisdiction, and constables are also elected by the voters of the city. Various administrative boards are appointed by the mayor, subject to confirmation by the aldermen. Minor positions are filled upon examination by civil-service boards. The tax assessment is made by ward assessors, who, with the mayor, city clerk, and tax commissioner, constitute a board of review of assessment rolls.

In 1914 the bonded debt of Milwaukee was \$10,577,500 and its floating debt \$1,714,600. The statutes limit the borrowing power of the city to 5 per cent of the average assessed valuation of property for five years. While the basis of assessment prescribed by law is the full value of real and personal property, practice has fixed it at about 90 per cent of the full value. The rate in 1914 was \$13.79. During 1913 the receipts of the city from all sources were \$16,881,587. Of this amount, \$6,859,937 came from general property taxes and \$6,774,437 from sales of investments. The expenditures during the same year amounted to \$10,369,505, of which \$2,344,697 was expended for schools, \$618,142 for the police department, \$725,186 for the fire department, \$468,968 for interest on the city's debt, and \$901,074 for water works. In 1913 the assessed valuation of all property was \$460,548,763, of which \$368,664,865 was real property and \$91,883,898 personal. The water works of the city, begun in 1872, and now including 505 miles of mains, have cost Milwaukee \$7,485,000.

Milwaukee is favorably situated with reference to extensive resources of farm, mine, and forest. It enjoys the advantages of water transportation afforded by the Great Lakes, in addition to excellent railroad facilities. Among the railways that enter the city are the Chicago, Milwaukee, and St. Paul, the Chicago and Northwestern, the Minneapolis, St. Paul, and Sault Ste. Marie, and, by lake ferry, the Grand Trunk and the Pere Marquette. The city has become important both as a collecting and a distributing centre, and is noted also for its manufacturing enterprises. There is an excellent harbor protected by a breakwater. In the shipments eastward there is competition between the lake system of transportation and the railroads, while a considerable traffic crosses Lake Michigan and finishes its transit east by rail. In the lake commerce the shipments far exceed the receipts. The principal commodity received from the East is coal, which reaches Milwaukee by way of the lakes. The following table shows the receipts and shipments of the principal articles for the year 1913.

COMMODITIES	Receipts	Shipments
Flour..... barrels	3,161,297	3,490,922
Wheat..... bushels	7,372,650	2,998,911
Corn..... "	13,140,650	8,956,897
Oats..... "	15,972,900	13,599,345
Barley..... "	18,897,700	6,017,315
Rye..... "	3,081,100	2,397,709
Lumber..... feet	*301,830,000	*61,854,680
Coal..... tons	*5,860,263	*1,000,589

* Lake traffic only.

With respect to corn and oats the city is primarily a distributing rather than a consuming centre. It will be noted, however, that there is a marked difference between the receipts and

the shipments of barley and wheat, Milwaukee being a large consumer of these products in the milling and brewing industries. Barley is used principally in the manufacture of beer, which is one of the most notable industries of the city. No other American city enjoys so high a reputation for its beer, although the manufacture of this product is not the most important industry. In 1913 the product of Milwaukee's chief manufacturing industries, according to local figures, was valued as follows: iron, steel, and metal products, \$46,519,509; leather and shoes, \$40,569,000; meat and packing-house products, \$30,500,000; beer, \$25,381,615; and flour and mill products, \$8,412,100. The value of all manufactured products in that year was \$420,116,266.

History. Lieut. James Gorrell, an English officer who visited the site in August of 1762, writes of "Milwacky" as an Indian town with an English trader residing there. This trader may have been Alexander Henry, a native of New Jersey, who made yearly visits to Milwaukee from about 1760 to 1765. Henry was followed by Alexander La Framboise, who in 1784 had substantial holdings at the mouth of the Milwaukee River. In about 1789 two French Canadians, Jean Baptiste Mirandean and Jacques Vieau, visited the place. Mirandean's stay was practically continuous until his death in March, 1819. Vieau made annual visits until about 1805, when he established himself permanently. On Sept. 12, 1818, Laurent Solomon Juneau (q.v.) arrived in Milwaukee and became Vieau's clerk and later his son-in-law. Juneau is considered the first permanent white settler of Milwaukee and, with his wife, exerted a vast influence over the neighboring Potawatami and Menominee tribes. From the Indians Juneau received extensive grants of land, but in subsequent treaties with the Indians these passed to the general government. The practical extinction of the Indian titles made Milwaukee an attractive place for settlers from eastern States. Moreover, the close of the Black Hawk War in 1832 directed attention to the west shore of Lake Michigan and in 1836 settlers came in considerable numbers. At an election for local officers held Sept. 17, 1835, 39 persons voted. On Jan. 16, 1838, Milwaukee was incorporated as a village by the Territorial Legislature and eight years later was granted a city charter. Juneau was elected the first mayor.

Consult: Wheeler, *Chronicles of Milwaukee* (Milwaukee, 1861), and Buck, *Pioneer History of Milwaukee* (3 vols., ib., 1876-84), the third volume of which is entitled *Milwaukee under the Charter*.

MILYUKOV, mīl'yōō-kōf', PAVEL NIKOLAEVITCH (1859-). A Russian historian and political leader, born near St. Petersburg. He studied in Moscow and was tutor in history at the university (1886-95). Banished from Russia because of his liberal views, he served as professor of history at the university of Sofia, Bulgaria, in 1897-98, traveled extensively both in Europe and in America in 1902-05, and from 1901 to 1906 was a member of the faculty of the University of Chicago. There he delivered lectures on historical and political subjects, among them a course on *Russia and its Crisis* (published 1905). He returned to Russia in that year, on the outbreak of the revolutionary movement following the St. Petersburg massacre of January 22, was imprisoned for some time, was active in forming the powerful Union of Unions

comprising the professional classes in the Empire, and was elected to the first Duma as a Constitutional Democrat. His election was annulled and he was even arrested while the Duma was in regular session, but was liberated after a month's confinement in prison. Despite this governmental reprobation, he remained the most prominent representative of the Constitutionalist party in that Duma and for long afterward. He was a member of the Balkan Committee of Inquiry which investigated the conduct of the War of 1913. He edited the Constitutional-Democrat organs the *Free Nation* and *Popular Rights* until they were stopped by Russian censorship, and later he became editor of the influential St. Petersburg newspaper *Retch*. Milyukov was a prolific writer. Besides contributions to magazines, he published: *Main Currents of Russian Historical Thought* (1893-95); *Sketches of the History of Russian Culture* (1895-96); *Russia and its Crisis* (1905); *Democracy and the Second Duma* (1906); *A Year of Struggle* (1907); *The Balkan Crisis and Politics* (1910).

MIMAMSA, mē-mām'sā (Skt. *mīmāṃsā*, investigation, discussion). The collective name of two of the six orthodox systems of Hindu philosophy. The two Mimamsa divisions are: first, the *Pūrva-mīmāṃsā*, "Prior Inquiry" or *Karma-mīmāṃsā*, "Inquiry concerning Works"; the second is *Uttara-mīmāṃsā*, "Later Inquiry" or *Brahma-mīmāṃsā*, "Inquiry concerning the Supreme Spirit," or, more commonly, simply *Vēdānta* (see VEDĀNTA). The former deals chiefly with the Vedic ritual and its significance, the latter with speculations as to the nature of the Supreme Spirit.

The reputed founder of the system is Jaimini, and the principles are embodied in a series of *Sūtras*, or aphorisms, in 12 books, discussing the sacred ceremonies of the Veda and the merit accruing from their proper performance. The oldest extant commentary on this obscure work is the *Bhāṣya* of Čabara-Svāmin, whose date is placed long after the birth of Christ. This composition in turn was critically annotated, about 700 A.D., by the great Mimamsa authority, Kumārila. An early treatise on the subject was an essay on the Mimamsa by Colebrooke in 1826, reprinted in his *Miscellaneous Essays* (London, 1873). MIMBAR, mīm'bār. See MOSQUE.

MIME, mīm (Lat. *mimus*, from Gk. *μῖμος*, *mimos*, imitator, actor, sort of drama). A species of popular comedy among the ancients, in which scenes of common life were represented with imitative gestures and dancing, and with jocose dialogue more or less freely improvised. It was said to have been invented by Sophron of Syracuse, who wrote in the Doric-Greek dialect. Mimes were a favorite amusement of convivial parties, the guests themselves being commonly the performers. In the hands of such writers as Laberius and Publilius Syrus the mime included much homely wisdom in the shape of

familiar saws and proverbial lines. In the theatres mimes came to be used later as after-pieces. The actors, themselves called mimes (*mimi*), appeared in front of the stage, without buskins or masks, but attired in patchwork cloaks (*centunculi*), as were the harlequins (q.v.) of a later day. Consult: C. J. Grysar, *Der römische Mimus* (Vienna, 1854); Patin, *Etudes sur la poésie latine* (Paris, 1875); Friedländer, *Sittengeschichte Roms*, vol. ii (Leipzig, 1890); Teuffel and Schwabe, *History of Roman Literature* (Eng. trans., London, 1900); Edmond Faral, *Mimes français du XIIIe siècle* (Paris, 1910).

MIMEOGRAPH. See COPYING MACHINES.

MIMESIS. See ORTHOGRAPHY, FIGURES OF.

MIMETITE. A lead arsenate and chloride closely resembling pyromorphite, occurring in yellow, brown, or white hexagonal crystals.

MIMICRY (from *mimic*, from Lat. *mimicus*, mime). A form of protective resemblance by which one species so closely resembles another in external form and coloring as to be mistaken for it, although the two may not be really allied and often belong to distinct families or orders. As early as 1746 Rüssei von Rosenhof in his *Insekten-Belustigungen* drew attention to the resemblance which geometric caterpillars, and also certain moths when in repose, present to dry twigs, and thus conceal themselves; and afterward Erasmus Darwin, in his *Zoönomia* (1794), sketched out the subject.

Bates's Theory of Mimicry. These facts received little attention, however, until 1862, when Bates proposed a general theory to account for them. He found during many years' residence in Brazil strikingly colored butterflies belonging to the brilliantly colored family Heliconiidae, and associated with them and indistinguishable, except on close examination, certain butterflies belonging to the structurally very different family Pieridae; also certain swallowtail butterflies and day-flying moths. None of the mimicking insects were as abundant as the Heliconiidae they resembled. The Heliconiidae have an offensive taste and odor, in consequence of which they are immune from attacks by insectivorous animals; they fly deliberately, and they make no attempt

theory assumes that some of the Pieridae happened at the start to resemble the primitive Heliconiidae and received a partial immunity as a result; that such Pieridae alone survived and produced descendants of like character; and that a selection of the most heliconid-like of these followed. By a continuation of this process the pierida and the other Lepidoptera gained their present close resemblance to the Heliconiidae. The theory is a broad one and accounts for cases of mimicry in other groups of Lepidoptera as well as in other orders of animals. It is not necessary, however, to go to South America for examples of mimicry. In North America, as well as in Asia and Africa, occurs the genus *Danais*, which is also a protected form. The common American species *Anosia pleurippus* is closely mimicked by *Basilarchia dirippus*, a butterfly of rather remote affinities. Three genera of Danaiidae in tropical Asia, *Euplexes*, *Danais*, and *Hestia*, are very different, but are all protected. In each genus certain species are mimicked with extraordinary accuracy by species of the genus *Papilio*.

But mimicry is not confined to the Lepidoptera. Especially well protected wasps and bees have many imitators, and there are cases of mimicry even in vertebrates.

Müller's Theory of Mimicry. In 1879 Fritz Müller, as the result of many years' observation in southern Brazil, proposed a modification of and addition to the foregoing explanation of Bates. Bates himself, when first describing the cases he observed, had suggested that they might be due to some forms of parallel variation dependent on climatic influences, and Wallace (*Island Life*, p. 255) adduced other cases of coincident local modifications of color, which did not appear to be explicable by any form of mimicry. Müller's theory is founded on the assumption that insect-eating birds only learn when young and by experience to distinguish the edible from the inedible butterflies, and in doing so necessarily sacrifice a certain number of distasteful butterflies. "Now," says Müller, "if two distasteful species are sufficiently alike to be mistaken for one another, the experience acquired at the expense of one of them will likewise benefit the other; both species together will only have to contribute the same number of victims which each of them would have to furnish if they were different. If both species are equally common, then both will derive the same benefit from their resemblance—each will save half the number of victims which it has to furnish to the inexperience of its foes. But if one species is commoner than the other, then the benefit is unequally divided, and the proportional advantage for each of the two species which arises from their resemblance is as the square of their relative numbers." Wallace, who fully accepts Müller's theory, in his statement of the theory (*Darwinism*, p. 253) adds: "But if the

at concealment, although their bright distinctive colors permit them to be recognized and avoided as obnoxious. If any other butterflies in the same region were to become indistinguishable from the Heliconiidae they would profit by a corresponding immunity from attack. The

theory assumes that some of the Pieridae happened at the start to resemble the primitive Heliconiidae and received a partial immunity as a result; that such Pieridae alone survived and produced descendants of like character; and that a selection of the most heliconid-like of these followed. By a continuation of this process the pierida and the other Lepidoptera gained their present close resemblance to the Heliconiidae. The theory is a broad one and accounts for cases of mimicry in other groups of Lepidoptera as well as in other orders of animals. It is not necessary, however, to go to South America for examples of mimicry. In North America, as well as in Asia and Africa, occurs the genus *Danais*, which is also a protected form. The common American species *Anosia pleurippus* is closely mimicked by *Basilarchia dirippus*, a butterfly of rather remote affinities. Three genera of Danaiidae in tropical Asia, *Euplexes*, *Danais*, and *Hestia*, are very different, but are all protected. In each genus certain species are mimicked with extraordinary accuracy by species of the genus *Papilio*.

But mimicry is not confined to the Lepidoptera. Especially well protected wasps and bees have many imitators, and there are cases of mimicry even in vertebrates.

Müller's Theory of Mimicry. In 1879 Fritz Müller, as the result of many years' observation in southern Brazil, proposed a modification of and addition to the foregoing explanation of Bates. Bates himself, when first describing the cases he observed, had suggested that they might be due to some forms of parallel variation dependent on climatic influences, and Wallace (*Island Life*, p. 255) adduced other cases of coincident local modifications of color, which did not appear to be explicable by any form of mimicry. Müller's theory is founded on the assumption that insect-eating birds only learn when young and by experience to distinguish the edible from the inedible butterflies, and in doing so necessarily sacrifice a certain number of distasteful butterflies. "Now," says Müller, "if two distasteful species are sufficiently alike to be mistaken for one another, the experience acquired at the expense of one of them will likewise benefit the other; both species together will only have to contribute the same number of victims which each of them would have to furnish if they were different. If both species are equally common, then both will derive the same benefit from their resemblance—each will save half the number of victims which it has to furnish to the inexperience of its foes. But if one species is commoner than the other, then the benefit is unequally divided, and the proportional advantage for each of the two species which arises from their resemblance is as the square of their relative numbers." Wallace, who fully accepts Müller's theory, in his statement of the theory (*Darwinism*, p. 253) adds: "But if the

two species are very unequal in numbers, the benefit will be comparatively slight for the more abundant species, but very great for the rare one. To the latter it may make all the difference between safety and destruction."

The facts of mimicry are very remarkable; as to causes there is much difference of opinion. The theory of Bates is accepted by many; also that of Müller. Others, like Eimer, Elwes, and Piepers, deny that the mimicry is due to natural selection, but rather to definitely directed evolution, the result of "outward influences such as climate, nutriment, etc., acting on a given constitution." Others, rejecting the Müllerian theory, accept Bates's facts, but ascribe more to the influence of the local environment, such as the action of light, heat, dryness or moisture, etc., yet allowing that in the end natural selection may act as a preservative agent.

The objections to the Müllerian theory are the following: neither Bates nor Wallace himself, though each lived for several years and collected butterflies in the American tropics, ever actually saw a bird chase and devour a butterfly, although insectivorous birds are said by them to be abundant in Brazil and the Eastern Archipelago. Piepers, Pryor, Skertchley, and other tropical naturalists of long and intelligent experience agree that very rarely has any bird been seen even to chase a butterfly; while Judd concludes from an examination of stomachs of insectivorous birds that none of the American birds feeds upon butterflies "during any month of the year to the extent of one-tenth of 1 per cent of its food." Ornithologists confirm this abstinence from eating butterflies. From these and numerous other cases it appears that butterflies enjoy a peculiar immunity from the attacks of birds.

It is sometimes the case that it is difficult to tell which is the model and which the mimic. On the Solomon Islands a dark-brown *Euplœa* and a *Danais*, both inedible, were accompanied by a *Hypolimnas* butterfly, also inedible, all three genera being avoided by birds both in the larva and imago stages. The fact, says Packard, that the mimickers belong to more primitive groups than the models, and that they are as a rule rare and apparently on the verge of extinction, indicates that they are the relics of an earlier geological period, and having been exposed to the same local and modifying changes in the environment as the models, have thus been preserved. Most of the cases of mimicry are really cases of convergence produced by similar conditions of life. Moreover, the ground colors of butterflies are restricted in range to reds, shades of brown, yellow, white, and more rarely blue and green. Also the patterns are limited; nature has repeated them over and over again. It is no wonder that there should be apparent cases of mimicry, in regions so similar as the hot and damp forest-covered plains of Brazil or the upland hot plains of southern Africa and the deep forests of the East Indies. On the other hand, Poulton heads the defenders of the theory and in many ways makes out a most excellent case.

As authorities differ so greatly in their interpretations of the facts, the subject may be considered an open one. That the bad-tasting butterflies are not eaten by birds any more than hairy and bad-tasting caterpillars, is an acknowledged fact; that the edible species mimicking and flying with them are in very rare cases de-

voured by birds, may be allowed, but its importance as a factor in evolution has been in some quarters unduly magnified. For other cases of mimicry, see PIGMENT; PROTECTIVE COLORATION AND RESEMBLANCE.

MIMIR, mē'mir. A water giant of Norse mythology, who dwelt beneath the world ash Yggdrasil and guarded a spring, considered the source of memory and wisdom and called Mimir's well. Odin in his wanderings asked for a drink from the well and was obliged in exchange to give one of his eyes, the moon, which Mimir sank deep in the spring.

MIMNERMUS (Lat., from Gk. Μίμνερμος) of COLOPHON (or Smyrna). A Greek elegiac poet, who lived in the latter half of the seventh century B.C. His work *Nanno*, in two books, was so named from a flute player whom he had loved in vain; it is a collection of elegies that were models for later poets in sustained calmness and tender sentimentality as opposed to the political elegiac verse previously in vogue. Mimnermus is credited with having brought the elegy back to its original design of expressing personal grief, and to have been the first to make the elegy (q.v.) an expression of love; his musical temperament found the elegy a fitting medium. For the fragments, consult: Theodor Bergk, *Poeta Lyrici Græci* (new ed., Leipzig, 1914); W. C. Wright, *A Short History of Greek Literature* (New York, 1907).

MIMOSA, mī-mō'sā (NL., from Gk. μίμος, *mimos*, imitator). A genus of Leguminosæ (pea family) comprising about 300 species, trees, shrubs, and herbs, with bipinnate leaves, natives of the warmer and more arid regions of America, Africa, and Asia. In general, the species are called "sensitive plants," on account of their motile leaves, the leaflets of which change position rapidly if touched. The motility of the leaves is thought to be related to protection against excessive loss of water, and is an adjustment to dry regions. This remarkable power enables the plant to reduce its leaf exposure according to the needs. The species of *Mimosa* belonging to the United States are chiefly natives of the States bordering upon Mexico. The name is also applied popularly to species of the related genera *Acacia* and *Albizia*. See SENSITIVE PLANT.

MIMS, FORT. See FORT MIMS, MASSACRE OF.

MIMUS. The Roman name for the mime (q.v.).

MIN, mēn. An Egyptian deity, the local god

of Panopolis or Akhmim (q.v.) and of Koptos (q.v.). He was the god of agriculture, typifying the generative forces of nature, and annual harvest festivals were held in his honor. He is generally represented as an ithyphallic human figure wearing a headdress of two enormous feathers and holding in his right hand a flail. Behind him is a shrine with trees upon it or near it. His sacred animal was the ram. In later times he was often identified with Ammon-Ré. The Greeks identified him with their god Pan. Consult: Adolf Erman, *Life in Ancient Egypt* (London, 1894); Wiedemann, *Religion of the Ancient Egyptians* (New York, 1897); E. A. Wallis Budge, *The Gods of the Egyptians* (London, 1904).

MINA, or **MNA** (Lat. *mina*, from Gk. *μνά*, *mna*, measure of weight, sum of money, from Heb. *māneh*, weight, from *māndh*, to divide, measure out). A Greek weight and denomination in silver money, equal to 100 drachmas (q.v.), and the sixtieth part of a talent (q.v.). The value varied according to the talent used. The Attic mina was worth about \$18. It was used for purposes of account, and was never minted as a coin. See NUMISMATICS, *Ancient Coins—Origin—Classification*, first two paragraphs.

MINA, *mē'nā*, FRANCISCO ESPOZ Y (1781-1836). A Spanish guerrillero and general, born at Idocñ (Navarra), uncle of Francisco Javier Mina (q.v.), and a member of the class of yeomen. As such, and because of his democratic and radical principles, he disliked the hidalgos, but he was brave and honest, and conducted his warlike operations in as humane a manner as possible. When his nephew was captured by the French in 1810 Mina took his place as leader of a band of guerrilleros and shortly afterward he was appointed by the Junta de Aragón to the command of all the guerrilleros of Navarra. His first act was to shoot a man who was pretending to be a patriotic guerrillero but was only a bandit. The next year the government at Cadiz recognized him and in 1812 he was made commander in chief in upper Aragon. His position here made it possible for him to confiscate large quantities of war supplies that were imported by the French authorities and to levy duty on all other materials imported. With this money he paid his troops regular wages and avoided levying heavy contributions on the country, while he maintained an excellent morale among his men. In the campaigns of 1813-14 he did good service under the Duke of Wellington and was frequently wounded. Having fallen from favor when Ferdinand VII was restored, he made an unsuccessful attempt at a liberal uprising and went into exile. In 1820 he returned and served the Liberal party throughout northern Spain, offering the only serious resistance to the French, who intervened in Ferdinand's favor. In 1823 the French forced him to capitulate and allowed him to escape. Despite his having made in 1830 another attempt against Ferdinand, when the latter died (Cristina recalled Mina to Spain and gave him command against the Carlists in 1835. His health was already broken, however, and he died in December of the next year, after forcing the Regent in August to grant a constitution to the country. Consult his *Memorias*, published by his widow (Madrid, 1851-52).

MINA, FRANCISCO JAVIER (1789-1817). A Spanish soldier. He was born at Idocñ, in

Navarra, took part with his uncle, Francisco Espoz y Mina, in the guerrilla warfare of 1808-09 against the French, but was taken prisoner in 1810 and detained four years at Vincennes. In 1814 he was in arms against Ferdinand VII, but was forced to flee to France. Thence he went to England, where he interested himself in the cause of the Mexican patriots, and with the aid of some prominent Englishmen organized an expedition and sailed for America. In the United States he received sympathy and substantial support, and took 200 volunteers with him, arriving at Galveston in November, 1816. Soon afterward, crossing over to New Orleans, he obtained more assistance, and after being reinforced by 100 Americans at Galveston, landed at Soto Marina, Province of Tamaulipas, April, 1817. At the head of 300 men he defeated Generals Armiñán and Ordóñez, and took the towns of León and Guanajuato with the fortress of Sombrero. Deserted by most of his followers, he was surprised on October 17 by an overwhelming force, taken to Mexico and shot, Nov. 11, 1817.

MINA BIRD. See MYNA.

MINÆANS. A Yemenite people who played an important part in the early history of Arabia. The native name was *Ma'in*; hence the Greek *Μαίαιος* or *Μαίαιος*. It is possible that the name was originally *Ma'an*, which has been identified by some scholars with *Magān*, a country south-east of Babylonia, referred to as early as the inscriptions of Naram Sin of Agade in the fourth millennium B.C. and Gudea of Lagash c.3000 B.C. But the identification is doubtful. There is good reason for supposing that the Minæans are mentioned in Judg. x. 12; in 1 Chron. iv. 41, in connection with the Amalekites against whom the tribe of Simeon made a raid in the time of Hezekiah; in 2 Chron. xxvi. 7, in connection with Philistines and Arabs in the days of Uzziah; and in Job ii. 11, where the Greek rendering suggests that Zophar was a Minæan. While there are many references in the Assyrian inscriptions to Kedar, Nebayoth, Aribi, and Sheba (q.v.), there is no mention of a kingdom of *Ma'in*. Among classical writers, Eratosthenes (c.275-195 B.C.), Agatharchides (c.120 B.C.), Strabo (died c.24 A.D.), Pliny (23-79 A.D.), the *Periplus Maris Erythræi* (c.100 A.D.), and Ptolemy (second century A.D.), speak of the Minæans as one of many peoples in southwest Arabia, but have no knowledge concerning the earlier history of this nation. The fact that there was an extensive and flourishing Minæan kingdom in Arabia is known only through the native inscriptions. These have been secured chiefly through the personal efforts of Halévy, Doughty, Euting, and Glaser. Many of these inscriptions still remain unpublished. Most of them are very brief and are readily interpreted, but a few of the longer ones present considerable difficulty. As to the period from which these inscriptions come there was practical unanimity among scholars until 1889. It seemed impossible that they could be older than the earliest Sabæan inscriptions (see SABÆANS), and it was supposed that the Minæan and Sabæan kingdoms flourished side by side. Such eminent scholars as D. H. Müller, Mordtmann, Hartmann, Eduard Meyer, and Huart still adhere to this view, granting that some may be as old as the ninth century B.C., but maintaining that the bulk of them were written in the following centuries. They point out that while the

earlier inscriptions of the Sabæan officials known as *mukarrib* are written boustrophedon, there is no Minæan inscription thus running both ways; that in the famous inscription, Halévy 535, there seems to be a reference to the Medes which would place it in the sixth century; that Eratosthenes apparently knows of Minæan kings reigning at Karna, and that the name Ptolemy occurs in a Minæan inscription on an Egyptian sarcophagus. Glaser, however, in 1889, presented strong reasons for believing that the Minæan kingdom preceded the Sabæan; and Hommel, Winckler, Schmidt, Derenbourg, Margoliouth, Weber, Grimme, and Caetani have advanced arguments in favor of his position. The silence of the Sabæan inscriptions concerning a Minæan kingdom would be very strange, if these nations were for a long time powerful rivals; and the casual references to Sheba in Minæan inscriptions do not seem to harmonize with the position of this power in the centuries preceding 115 B.C. That the Assyrians make no mention of *Ma'in*, while they are frequently occupied with Sheba, apparently indicates the decline of the former and the rising importance of the latter. In its most flourishing period the Minæan kingdom extended far to the north, as is evident not only from the inscriptions found at El Oela, but also from the mention of the *Ma'inu Muzran* in Halévy 535. So extensive a kingdom with its centre in the South Arabian Jauf, where its great cities *Ma'in*, *Karnawu*, and *Yathil* were, can scarcely have existed side by side with a strong Sabæan kingdom with the neighboring *Marib* for its capital. A long inscription found at *Sirwah*, unfortunately not yet published, according to competent testimony, describes the destruction of the Minæan kingdom by a Sabæan *makrib* about 550 B.C. Sargon's (721-705 B.C.) contemporary *Itamar* is not yet designated as king. As Müller has clearly proved that the *mukarrib* preceded the kings of Sheba, the inference seems necessary that the Minæan kingdom flourished before the Sabæan *mukarrib* period and fell before the rise of the Sabæan kingdom. The Minæan system of writing shows in many respects a closer affinity to the earlier than to the later Sabæan script; and the oldest Sabæan inscriptions indicate a long period of development of the South Arabian system of writing. Hence the fact that the earliest Sabæan inscriptions are written boustrophedon does not show that this script has been recently introduced. A comparison of the language clearly manifests the higher age of the Minæan, which has preserved the *s* in the causative and in the pronominal suffixes against the *h* in the Sabæan. The identification of the *Madhay* as *Medes* is extremely doubtful; and Grimme's suggestion that it represents the people of *Midian* seems to possess far more probability. That the Minæans continued to exist as a people long after their power in Arabia had passed to others is evident from the Greek writers. Whether Eratosthenes drew upon older sources accessible to him in Alexandria, was imperfectly informed, or actually knew of petty kings reigning in Karna in his day, no scholar would seriously maintain that the power reflected in the Minæan inscriptions could have been exercised from Karna in the third century B.C. If the sarcophagus inscription is really Minæan rather than Hadramautian and Talmith is Ptolemy, its content shows not more clearly the survival of ancient forms, along

with some very late ones, among the Minæans of the period, than the absence of any important Minæan kingdom at that time. It therefore seems exceedingly probable that the 26 kings of *Ma'in* known from the inscriptions reigned before there was any Sabæan king in *Marib*. As it is scarcely credible that chance should have given us the name of all Minæan kings or that the 26 names represent an unbroken succession, it would be hazardous to infer that the earliest of them cannot have reigned more than four or five centuries before the last. There may have been more than one dynasty. As among the Sabæans, so in the kingdom of *Ma'in* each year seems to have been named after two *mukarrib* or high officials, like the *limmi* in Assyria, the archons in Athens, the ephors in Sparta, or the consuls in Rome. The absolute age of the Minæan kingdom cannot be determined. The early occurrence of numerous place names in southern Syria and northwestern Arabia which seem to have been transferred from Yemen, the raids of Minæans upon Palestine in the period of the Judges, and the essentially Yemenite character of the traditions brought by clans afterward forming a part of the people of Israel, from the land of Midian and the Negeb to Canaan, render it probable that kings of *Ma'in* extended their power to the borders of Palestine as early as the thirteenth century B.C. The Minæans were to a large extent a settled people living in cities, cultivating the soil, worshiping in sanctuaries. Their chief gods were a male deity, *Athtar* (see *ISHTAR*), the solar goddess *Shamsi*, *Wadd*, and *Ankarih*. They had priests and priestesses, hierodules and sacred prostitutes, a sacrificial cult, and many rules of taboo. A deeper religious sense is apparent than in the period of skepticism and syncretism preceding Mohammed.

The language of the Minæans is only dialectically different from the Katabanian, Hadramautian, and Sabæan, and is closely akin to the Ethiopic and the classical Arabic. As to the origin of the system of writing used by the South Arabian peoples, it is supposed by Halévy and Lidzbarski to have been formed from the North Semitic alphabet by a modification of certain signs to denote kindred sounds and by changes rendering the signs generally symmetrical. There is indeed good reason to suppose that many new signs were added in Arabia by slight changes in those already existing, and that the characters were given a squarer form. But there are some letters that are so different from those of the North Semitic alphabet as to raise the question whether other extraneous influences may not have been at work. Whatever the relations of the various Egypto-Libyan, Mycæan, and Anatolian alphabets, the contact of the Minæans with Egypt and the Philistine coast makes it probable that it was in the northwest rather than on the Persian Gulf that this alphabet grew up. A tablet found at *Lachish* shows that not only cuneiform signs but also the Mycæan signary was to some extent used in the Philistine cities in the fourteenth century B.C. It may have been from Gaza that the Minæans brought the prototype signs of their alphabet. As our oldest inscriptions in the North Semitic alphabet, dating from the tenth and ninth centuries, show that this system of writing must have been long in use, so our earliest Minæan inscriptions indicate that the South Arabian alphabet already had a long and as yet quite obscure history of development.

MINAËV, mé-ná'ef, DMITRI (1835-89). A Russian poet, born at Simbirak. He was educated in a military school, and, after brief service as secretary in the Department of the Interior, from which he resigned in 1857, devoted himself to literature. His most important work was as a translator of parts of Dante's *Inferno* and of some of the works of Victor Hugo, and, among English poets, of Shelley, Byron, and Marlowe. His original works include poetry, especially satire, and a comedy, which won a prize from the St. Petersburg Academy.

MIN'AHAS'SAS. The natives of the Province of Minahassa in northern Celebes, called by some authorities Alfuros. A mixture of types certainly exists. Physically, the Minahassas appear to be related to the Tagals and other Philippine tribes, and there is even a suggestion of Japanese features. In point of language they are undoubtedly members of the Malay stock, but differ notably from other divisions of this family in Celebes and again approximate Philippine tribes. Since cultural evidence points in the same direction, the Minahassas may safely be considered alien immigrants from the north. The Malayan language proper has in recent years made considerable inroad upon the native dialects. Among the Minahassas women are on an equal footing with men, although from Mohammedan influences some modifications have been made upon the ancient monogamy of this people. The best account of the Minahassas in English is in Hickson, *A Naturalist in North Celebes* (London, 1889). See ALFURESE; CELEBES; MOLUCCAS.

MINAMOTO YORITOMO, mé'ná-mó'tó yō-ré-tō'mō (1146-99). A Japanese warrior and statesman who played an important part in the struggles for power of the rival military fam-

ilies, the Taira and the Minamoto, to the latter of which he belonged. His father, Yoshitomo, having been treacherously murdered in 1159 at the instance of Kiyomori, chief of the Taira clan and at that time the virtual ruler of the country, Yoritomo fled, but was captured and condemned by Kiyomori to be beheaded. Spared through the pity of the stepmother of Kiyomori, he was banished to Idzu. There he married the daughter of Hojo Tokimasa, one of his guardians in exile. In 1180, calling around him his father's scattered retainers, and securing the assistance of his father-in-law and the monks of Hiyeizan (see KYORO), he got together an army which he placed under the command of his youngest brother, Yoshitsune, and proceeded against the Taira. Five years later his enemies were utterly annihilated in a great naval battle off Dan-no-ura, near Shimonoseki. He made Kamakura his capital, was created Sei-i-tai-shogun in 1192, laid the foundations of the feudal system in Japan, and became the virtual ruler of the land—nominally under the Mikado—and the office of shogun became hereditary in the Minamoto family. He died in 1199 with his great reputation somewhat sullied by his cruel treatment of his brother Yoshitsune. See MINAMOTO YOSHITSUNE.

MINAMOTO YOSHITSUNE, mé'ná-mó'tó yō'shē-tō'nā (1158-1189). A Japanese chieftain. Japanese history in the eleventh and twelfth centuries A.D. is concerned with the struggles of the Taira and the Minamoto clans. In 1159 Yoshitomo, the head of the Minamoto, was killed and his clan defeated. His three sons escaped, and after years of adventure defeated the Taira finally in 1185. Yoshitsune, the youngest of the three, was the lieutenant of his elder brother Yoritomo, and the most efficient warrior in his army. Yoshitsune was in command when the last battle was fought, but his success excited the jealousy of his brother, who sought his death. Escaping with 11 comrades, Yoshitsune was pursued and committed suicide in 1189. His history, with its adventures, triumphs, and tragic end, is the favorite theme of romance, poetry, and drama. In one form of the story the hero escaped with his life and found refuge among the Aino in Yezo, where he is still worshiped as a god. Another legend represents him as going to the continent of Asia and identifies him with Genghis Khan.

MIN'ARET. The tower of a mosque (q.v.). The Mohammedan call to prayer is chanted by the voice of the muezzin, who, five times daily, mounts to its upper balcony to summon the faithful with the prescribed formula. Each mosque has one or more minarets. The normal number for the largest Djami mosques is four, one at each angle of the edifice. Some have as many as six, e.g., the Ahmed mosque at Constantinople. The mosque at Mecca has the exceptional number of seven.

The usual type is a square, polygonal, or cylindrical structure of stone or brick, consisting of several stories marked by balconies, either projecting on stalactite supports or with a receding story above; it is crowned by a pinnacle or small dome. The summit is reached by a winding inner stairway; only the old stone minaret of Tulun at Cairo has an external winding staircase.

The earliest mosques had no minarets. They were first built during the seventh century, the Caliph Omar being said to have erected two, at

Kufa and Medina. Those earlier than the twelfth century were usually heavy square structures of stuccoed brick or stone without much ornament. This type is preserved at the mosque of Sidi Okba at Kairwan in Tunis. This square type persists in north Africa outside of Egypt, and was carried by the Moors into Spain. The Giralda at Seville (q.v.) is one of the largest and richest of this type, though the upper stages are a Renaissance addition. The minarets of Cairo are usually polygonal and highly ornate, with corbeled balconies and receding stages. Among the finest are those of Ibn Tulun, Hassan, Barkuk, Kalaun, Bordeni, and Kait Bey. The Hassan mosque has two minarets; that of Kait Bey only one.

The minarets of Egypt, Spain, Syria, India, Persia, and Turkey built between the thirteenth and sixteenth centuries are among the most original and graceful works of Eastern architecture. The Turkish type is the simplest—a cylindrical or fluted shaft with one to three corbeled balconies and a slender conical spire terminating in a gilded crescent. The Persian minarets are also cylindrical, with bulbous tops, and are veneered with brilliant ceramic tiles. Those of India show varied forms, some following Hindu models, others the Persian, but executed in marble or sandstone without tiles, as at Delhi and Agra. The most remarkable is the most ancient—the Kutub Minar at old Delhi (c.1200), a superb tower in four tapering and receding stories, each of a different star-shaped or scalloped plan. Damascus and Bagdad preserve some of their mediæval examples. The minarets of the Constantinople mosques, such as St. Sophia, Ahmed, etc., are exceedingly graceful. Sometimes the colleges, or madrasah, had minarets of style similar to those of the mosques, as in that of Sultan Husein at Ispahan, where the towers are similar to those of the great mosque of Ispahan. The height varies greatly; among the highest are the Giralda (formerly 230 feet, now 308 feet) at Seville, Kalaun (193 feet) and Hassan (280 feet) at Cairo, and the Kutub Minar, near Delhi (242 feet). See MOSQUE; and consult the bibliography of MOHAMMEDAN ART.

MINAS, mē'nāsh, more properly BELLO HORIZONTE, bē'l'ô ô're-zôn'tá. The capital of the State of Minas Geraes, Brazil (Map: Brazil, J 8). It stands on a plateau, at an altitude of 3017 feet, 60 miles northwest of Ouro Preto (q.v.), whence the capital was removed in 1897. It was founded, in 1894, upon modern plans, with wide, well-paved streets and large public gardens. Its public buildings include the post office, Law School, President's palace, Library of Congress, public market, and two theatres. It has also many fine residences. It is lighted by electricity and has an excellent supply of pure spring water. It has made a beginning of industrial life by the establishment of a few factories. Pop., 1912 (est.), 35,000.

MINAS, mē'nás. Capital of the department of the same name in Uruguay. It is picturesque situated 55 miles northeast of Montevideo, with which it is connected by rail (Map: Uruguay, J 4). It is surrounded by well-cultivated grain-producing lands, and there are quarries of marble and granite in the neighborhood. Pop. (municipality), 1900, 8955. The city was founded in 1784.

MINAS DE RIO TINTO, mē'nás dâ rê'ô tén'to. An important mining town in southern

Spain, in the Province of Huelva, situated among the mountains, 32 miles northeast of the city of Huelva (Map: Spain, B 4). The surrounding country contains almost inexhaustible deposits of copper ore, which were exploited by the ancient Phœnicians. In 1873 the mines were taken over by a London company and the methods of obtaining the ore revolutionized. The mines now employ 10,000 workers; in 1911 the quantity of ore produced amounted to 1,603,854 tons. The town, which in 1845 had a population of only 800, numbered, in 1900, 9956, and, in 1910, 12,626.

MINAS GERAES, mē'nāsh zhâ-rîsh'. A southeastern state of Brazil, bounded by Bahia on the north, Bahia, Espirito Santo, and Rio de Janeiro on the east, Rio de Janeiro and São Paulo on the south, and São Paulo, Matto Grosso, and Goyaz on the west (Map: Brazil, H 7). It is the fifth state of Brazil in size, having an area of 221,951 square miles. It lies wholly in the Brazilian plateau, with an average elevation of 2000 feet, and is traversed by a number of mountain ranges, which, although the highest in Brazil, are not very prominent, owing to the general elevation of the surrounding country. The principal ranges are the Serra da Mantiqueira, along the southern frontier, and the Serra do Espinhaço, running north and south through the centre of the state. At their junction is Mount Itatiaia, about 9000 feet high and the highest point in Brazil. Only the mountain ranges and the river valleys are forested; between them are extensive steppes covered only with grass and scanty shrubbery. Minas Geraes is watered by numerous rivers, including the São Francisco (with its numerous tributaries which take in the larger portion of the state), the head streams of the Paraná, the Doce, and the Jequitinhonha. All the rivers have numerous cataracts and rapids; only the São Francisco is navigable for any distance, and it has no direct connection with the Atlantic Ocean. The climate, in general, is temperate, averaging 71.6° F. for the whole state. A great portion of the south and centre enjoys a much cooler climate, while the thickly wooded river valleys are very hot and humid. Originally the chief economic interest was centred in gold and diamond mines. These industries, in decline for a long period, have been revived and also the exploitation of mines of iron, of which there are large deposits, manganese, and precious stones has been undertaken. The chief industries are agriculture and stock raising, the leading agricultural products being coffee, corn, beans, rice, potatoes, tobacco, cotton, and sugar cane. Stock raising is carried on extensively, and butter and cheese are produced in large quantities. The chief manufactures are those of cotton, textiles, and cigars. The railway lines traversing the southern part of the state have a mileage of 2700 miles. Minas Geraes had a population of 3,184,099 in 1890, 3,594,471 in 1900; 4,500,000 (est.) in 1911. The inhabitants are largely of mixed origin, and the number of aborigines is still considerable; negroes are also numerous. Minas Geraes was settled at the end of the sixteenth century, immigrants being attracted there by the gold and diamond deposits. It was separated from the Captaincy General of Rio de Janeiro in 1709 and was made an independent captaincy in 1720. In 1788 it was the scene of an unsuccessful insurrection led by Joaquim José da Silva Xavier, "Tiradentes," which had

for its object independence and the establishment of a republic. Other revolts against the central government occurred in 1833, 1842, and 1844, all of which were suppressed. The capital was Ouro Preto (q.v.), up to 1897, when the seat of government was removed to Bello Horizonte or Minas (q.v.).

MINBU, min'bu. A district of the division of Magwe, Burma. Tillage and fishing are the chief industries. Area, 3302 square miles; pop., 1911, 263,939. Capital, Minbu.

MINCH. An arm of the Atlantic Ocean which separates the island of Lewes in the Hebrides from the northwest of Scotland (Map: Scotland, C 1). Its shores are exceedingly irregular and its average width is about 30 miles. It connects with the Gulf of the Hebrides to the south by the Little Minch, which is about 15 miles wide, and which separates the Isle of Skye from that of North Uist and the neighboring islands in the outer Hebrides.

MINCIO, mēn'chō. A left affluent of the River Po, Italy, which it joins near Governalo, 10 miles southeast of Mantua, after a southeasterly course of about 120 miles. Its source is at Peacheria, where it flows from Lake Garda. It is the ancient Mincius, and during the Austro-Italian wars (1800-14) was an important strategical base, several battles being fought along its banks.

MIN'CIUS. The ancient name for the river Mincio. This stream is celebrated by Vergil in his *Eclogues*.

MINCKWITZ, mīnk'vīts, JOHANNES (1812-85). A German poet and classical scholar, born at Lückersdorf. He was educated at Leipzig, was appointed professor there in 1861, and in 1883 removed to Heidelberg. He first gained fame by his translations into German of Homer, Æschylus, Sophocles, Euripides, Aristophanes, Pindar, and Lucian. He also wrote *Vorschule zum Homer* (1863). In the field of German criticism Minckwitz wrote *Platen als Mensch und Dichter* (1836) and *Leben Platens* (1838), and edited Platen's (q.v.) posthumous papers (1852); and he also published: *Lehrbuch der deutschen Verskunst* (1844); a play, *Der Prinzenraub* (1839); and a volume of popular poems (1847). Consult *Briefwechsel zwischen Platen und Minckwitz* (Leipzig, 1836).

MINCOPIES, min'kō-pīz. The native inhabitants of the Andaman Islands. They are in general of very low stature, averaging 1.49 meters, and are subbrachycephalic with an index of 82.6. They have a very low grade of civilization, living in huts called chongs, which consist merely of a roof on four stakes, and going naked. They live by hunting and use a peculiar bow in the shape of an S, which presents a curious analogue to certain Eskimo bows and also to the bows of some Bantu tribes in East Africa. Linguistically it has been impossible to connect them with any other group, even among peoples of similar physical type. Consult: Man, "Aborigines of the Andaman Islands," in the *Journal of the Anthropological Institute*, vol. xi (London, 1882); Deniker, *Races of Man* (ib., 1901); A. R. Brown, "Notes on the Languages of the Andaman Islands," *Anthropos* (Salzburg, 1914). See ANDAMANS.

MIND (AS. *gemynd*, Icel. *minni*, Goth. *gumunds*, memory, from AS. *munan*, Icel. *munu*, Goth. *gamunan*, to remember; ultimately connected with Lat. *mens*, Gk. *mēros*, *menos*, mind, Skt. *man*, to think). The collective term for

the subject matter of psychology (q.v.). The common-sense view of mind makes it a mind substance, a spiritual agent, a real, simple, and unitary being, sharply opposed to material substance as "thought" is opposed to "extension," yet interacting with the physical universe under some form of the causal law. This conception of mind has its root in primitive reflection upon the phenomena of sleep, dreams, trance, and death, and upon certain types of behavior, especially, we may suppose, upon the behavior which expresses emotion. It received philosophical treatment at the hands of the scholastic psychologists, and, in its current form, is practically a legacy from Descartes. It is doubtless kept alive by its emotional value; it satisfies human aspirations and accords well with the natural anthropocentric notion of the world at large. It is still held by some psychologists: Ladd openly accepts it, and James, while rejecting it for his psychology, yet admits that, for his personal thinking, it appears "the line of least logical resistance." Nevertheless, such a view of mind is wholly foreign to the spirit and to the requirements of modern psychology. In the first place, it is unsupported by psychological evidence. Had there been the same emotional temptation to reject minds as there has been to posit them, we may be sure that the arguments ordinarily urged in their favor would have received but scant attention. Secondly, the assumption of a real mind is superfluous. "The substantialist view of the soul," says James, "is at all events needless for expressing the actual subjective phenomena of consciousness as they appear"; "the substantial soul explains nothing and guarantees nothing."

Numerous difficulties have been encountered, upon the metaphysical side, in the attempt to resolve the dualism of mind and body which is involved in this concept of the substantial mind. (See SUBSTANCE; SOUL; DUALISM; MONISM.) In consequence there arose, early in the history of psychology, a second view, according to which mind is not substance but active principle; mind is an activity. Aristotle, who first developed the theory, identified mind with the principle of life; mind is the regulative or formative principle of the biological process, and its relation to body is similar to that of form to matter. This view was also that of the neo-Scholastics (see AQUINAS, THOMAS); and, stripped of biological implications, it furnishes the initial basis of certain definitions of mind which may be found in present-day psychology. It is important, for the understanding of the theory, to distinguish between mind as an activity and the activity of mind. The substantial mind was early thought to be an active mind; feeling, perception, memory, imagination, etc., were all activities of the mind, and it was only through these activities that mind could be known. Furthermore, the attempt to subsume these activities under one or more principal activities or functions gave rise to what is called faculty psychology. (See FACULTY.) Aristotle's faculties, on the other hand, were not powers or activities of a mind; they were rather stages in the growth or development of mind; feeling is mind at a lower stage, thinking is mind at a higher stage. A third conception of mind became possible only when metaphysical discussion and logical classification gave way to scientific observation and description. Mind then came to be regarded (1) as

a form of experience or (2) as an aspect of experience. Those who adopt the first view characterize mental experience as that mode of experience which is directed towards an object; e.g., in idea something is ideated, in judgment something judged; and the mental phenomenon, therefore, is the *ideating* or the *judging*. But these are again mental acts; and so we find a return to the "activity" theory of Aristotle, with the difference that the act of seeing, hearing, judging, etc., is now held to be a form of direct experience. Those who adopt the second view deny that the phenomena of mind are a peculiar form of experience; they believe, on the contrary, that mind has to do with the whole world of experience, but only in so far as it is dependent upon an experiencing person. Even here, however, there are differences of opinion. If the experiencing person, otherwise undefined, is conceived as standing in some sort of relation to an object, then it is possible to reach a functional view of mind which in many respects is similar to the "activity" theory. But if the experiencing person is further defined as a physiological individual; if mental experience is regarded as that aspect of experience which is conditioned upon a nervous system, then the sights, the sounds, the warmth, the pains, etc., which we experience are themselves so many items of mind.

In so far, then, as the older theories of mind are concerned, modern psychology is what Lange, the historian of materialism, named it—a psychology without a mind, a *Psychologie ohne Seele*. Even the few writers who still cling to the substantialist view make no use of the assumption in their actual presentation of psychological facts and laws; it is only in their concluding remarks, at the point of transition from psychology proper to metaphysics, that mind, the "unit being," is introduced. At the same time it would be entirely erroneous to apply Lange's phrase, without qualification, to mental science. A psychology without some sort of mind would be impossible. The new psychology keeps the term "mind," but defines it, in functional or existential terms, as the sum total of an individual's mental experience. Just as a plant is a closed group of physiological functions, so is mind the collective name for the closed group of mental functions; or, just as the plant, again, is the organized whole of root, stem, leaves, and flowers, and not something above and behind these parts, so is mind the organized whole of our mental processes (q.v.), and not something above and behind these manifestations of mentality.

MINDANAO, mén'dá-ně'ò. One of the most important and, according to the latest official estimate, the second in size of the Philippine Islands. It is the southernmost of the large islands of the archipelago, between lat. 5° 21' and 9° 50' N. and between long. 121° 53' and 126° 28' E., about 220 miles northeast of Borneo and 270 miles north of Celebes (Map: Philippine Islands, D 7). It is bounded on the north by the channels and seas separating it from the islands of Leyte, Bohol, Cebu, and Negros, the narrowest of these channels being the Strait of Surigao, 7 miles wide, separating the northeast extremity of the island from Leyte. On the east Mindanao is bounded by the Pacific Ocean, on the south by the Celebes Sea, and on the west by the Sulu Sea.

Area and Configuration. The latest official estimate gives as the area of the mainland, 36,292 square miles, or 4677 square miles less than Luzon, and of the 264 dependent islands, 1165 square miles, making a total of 37,457, which, even excluding the dependent islands, is larger than that of the State of Indiana. Mindanao, like Luzon, is very irregular in outline, having a shore line of nearly 1600 miles in length. It consists of a main body about 300 miles long from north to south and 150 miles broad, with a long irregular peninsula stretching in a semicircle for 180 miles from the centre of the west coast, where it is connected by an isthmus between the Bay of Iligan on the north and the Bay of Illana on the south. There are numerous other large and small bays on all sides of the island, among which the large and deep Bay of Davao indenting the south coast is one of the finest and largest of the archipelago. Of the dependent islands the principal (with their areas in square miles) are the following: Camiguín (94), off the north coast; Dinágat (309) and Siargao (151), on the northeast; Sámal (147), in the Bay of Davao; Balut (42) and Sarangani (25), to the southeast; Olutanga (36), south of the western peninsula; and Basilan (478), forming with about 50 small islets a separate province at the extreme southwestern end.

Topography. The coasts as a rule consist of sandy beaches interrupted by numerous rocky headlands. Almost everywhere the forest-covered mountains approach close to the shores, and the interior is in general very mountainous, containing the highest peaks in the Philippines, such as Mount Malindang, 8560 feet high, in the northwestern part, and the volcano of Apo, 10,312 feet, west of Davao Bay. The mountain system consists of a number of irregular, broken, and roughly parallel chains traversing the island from north to south and inclosing between them large and fertile valleys. The configuration of the mountains in many places bears evidence of having been influenced and even originated by volcanic action. There are several active and a number of extinct volcanoes, while plains of volcanic matter as well as sulphur and hot springs occur, and the island is subject to frequent and violent earthquakes. During the severe earthquake which visited the islands during 1897 the town of Zamboanga was ruined by the shaking and by a great sea wave. Very little is known concerning the geology of Mindanao. Like southern Luzon, volcanic rocks of modern date cover the island.

Hydrography. The two principal river systems lie on either side of the central mountain

range, both of them running almost the entire length of the island. On the east is the Augsan, over 200 miles long, running northward into the Bay of Bután; on the west is the Río Grande de Mindoro, over 200 miles long and the second river in size on the archipelago, running south, then west into the Bay of Illana, and rivaling in size the Cagayán of Luzon. Both of these systems include several large lakes. Owing to the proximity of the mountains to the coasts most of the remaining rivers of Mindanao are short and torrential.

Climate. Being situated at the southern end of the archipelago, within 10 degrees of the equator, and being less exposed to cooling winds than the northern islands, Mindanao has a hot and humid climate. The warm and moisture-laden south winds are particularly enervating, though the land breezes from the mountains are cool and refreshing. The climate is more equable than that of Luzon and consequently less invigorating, and the island is seldom touched by the typhoons, which rage only among the northern islands. The rainfall is very heavy, often exceeding 100 inches and reaching sometimes 140 inches in a year. Several parts of the island are subject to destructive inundations.

Flora and Fauna (for general description see PHILIPPINES). The vegetation of Mindanao, even compared with the rest of the archipelago, is remarkably luxuriant. Almost the whole island is covered with forests so interwoven with canes and vines as to form in many places an impenetrable jungle. The flora partakes of the character of that of Celebes and the Moluccas; cinnamon, nutmeg, and other spices, and betel nuts grow wild, and the forests abound in the most valuable building timber and cabinet woods. The animal life is equally abundant and varied, including, besides the species common to all the islands, many species peculiar to Mindanao. Monkeys are very numerous, and especially characteristic is the white monkey (*Macacus philippinensis*). Reptiles, including venomous snakes, abound, and the rivers are infested with crocodiles.

The population as shown by the last census, 1903, was 499,634, an average of 14 per square mile. Of this population 252,940, or over one-half, were classed as "wild" or noncivilized. About one-third of the total are Christianized Malays, about one-half of the total are Moros (Mohammedan Malays), the remainder Chinese, "mestizos," and uncivilized tribes.

Agriculture and commerce have received little attention, although the agricultural possibilities are very great. Rice, sugar, coffee, hemp, corn, tobacco, and the betel nut are grown, and the quality and quantity both suggest great possibilities if properly managed. At present less than 2 per cent of the island is under cultivation, but there seems no reason why the island should not produce great quantities of sugar, hemp, rice, and copra. Cinnamon, nutmegs, and spices are found in the forests and would probably justify cultivation and care. The natives take no interest in agriculture in excess of that needed to meet their personal requirements. The forests produce valuable woods, but little has been done to find markets for them.

MIND AND BODY. See BODY AND MIND.

MIND CURE. See FAITH CURE; HYPNOTISM; MENTAL SCIENCE; MESMERISM; PSYCHOTHERAPEUTICS; SUGGESTION.

MIN'DEN. An ancient town in the Province of Westphalia, Prussia, on the left bank of the navigable Weser, 39 miles west of Hanover (Map: Prussia, C 2). It is an old-fashioned town, with narrow, winding streets, but the suburbs are modern. Its fortifications were demolished in 1873. Its public buildings include the thirteenth-century cathedral, a fine early Gothic structure with valuable works of art in its treasury; the town hall, the church of St. Martin, the government buildings, and the Gymnasium. Minden manufactures linen and cotton goods, dyestuffs, cigars, glassware, chemicals, chocolate, leather, lamps, cement, paper, chicory, and iron products. It also builds ships and repairs railway rolling stock. Charlemagne made Minden the seat of a bishopric, which was converted into a secular principality in 1648 and united with Brandenburg. Near Minden an Anglo-Prussian force under Ferdinand of Brunswick defeated a French army under Contades, Aug. 1, 1759. See SEVEN YEARS' WAR. Pop., 1900, 24,327; 1910, 26,454, chiefly Protestants.

MINDEN. A town and the parish seat of Webster Parish, La., 30 miles east-northeast of Shreveport, on the Louisiana and Arkansas Railroad (Map: Louisiana, C 1). Cotton, corn, sugar, and potatoes are raised extensively, and the chief industrial establishments are saw mills, cottonseed-oil mills, and compresses. The water works are owned by the town. Noteworthy attractions include the three parks and the splendid high-school building. Pop., 1900, 1561; 1910, 3002.

MINDONGA. See CHOBÍ.

MINDORO, mén-dó'ró. One of the Philippine Islands, among which it ranks seventh in size. It is situated south of the main body of Luzon, from which it is separated by a sea channel $7\frac{1}{2}$ miles wide (Map: Philippine Islands, C 4). Its extreme length from northwest to southeast is 100 miles, and its greatest width is 58 miles. The area of the mainland is 3851 and of the 26 dependent islands 173 square miles, making a total of 4024 square miles. The island has an oval shape with no large indentations, though there are a number of small bays and several almost landlocked harbors. The coasts, though generally having deep water close to shore, are lined, especially along the west side, with submarine reefs. Mindoro is, next to Mindanao, the most elevated of the Philippine Islands. The whole interior forms a mountainous plateau, reaching in Mount Halcón the height of 8800 feet. Almost the whole of the island, from the mountain summits to high-water mark, is covered with unbroken virgin forests, though in the narrow strip of lowland along the western coast there are some prairie and marshy regions. The rivers are all short and simple streams running down from the edge of the plateau on all sides, there being no large river system. The climate is more variable than that prevailing in the southern islands, and Mindoro is especially exposed to typhoons. The proximity of the forests to the coast towns renders these unhealthy and subject to intermittent and typhoid fevers. The yield of rice was at one time so great that the

island was called the "granary of the Philippines," but the industry was destroyed by Moro pirates.

In spite of the fertility and natural wealth of the island its economic conditions are in a very backward state. A very small portion of it is cultivated, and the yield of agricultural products is scarcely enough for home consumption. The cultivation of sugar, cotton, and hemp is increasing, and a little of the latter is exported. The mineral wealth is believed to be considerable, but only the coal beds and sulphur springs have begun to be exploited. The principal exports are forest products, such as timber and pitch, and the forests also are the basis of the principal industries—woodcutting and rattan splitting. Communication is almost exclusively carried on in coasting vessels, the interior being a rough and pathless wilderness.

The population of Mindoro in 1903 was 28,361, including 7264 savages. The inhabitants are chiefly Tagalogs, who number 18,185, with 7266 Mangyans, 2088 Visayans, and 630 Ilocanos. The inland of Mindoro, together with its dependent islands, forms the Province of Mindoro, which had in 1903 a population of 39,582. The most important tribes were represented as follows: Tagalogs, 26,408; Mangyans, 7268; Visayans, 4962. See PHILIPPINE ISLANDS.

MIND READING. See MUSCLE READING; TELEPATHY.

MIND-STUFF THEORY. A metaphysical theory which explains the relation of matter and mind by affirming their identity under the form of atoms of mind stuff. These atoms are of a nature between physical atoms and psychical monads, representing an indivisible element, as the former, but being qualitatively rather than quantitatively determined, as the latter. Mind and matter, according to this theory, are but forms of composition of the atoms of mind stuff; only under the most rarely favorable conditions does this composition result in intelligence, as in the higher animals, but at the same time no matter is to be conceived as "dead" matter, since it is built up of elements whose essential character is psychical. Mind stuff seen from the inside constitutes what we call mind; seen from the outside it is what is called matter. The theory is expounded by W. K. Clifford in *Mind*, o. s., vol. iii.

MINE. See MINING.

MINE, SUBMARINE. Formerly all explosive devices designed to destroy or injure a ship by blowing a hole in her hull below the water line were called torpedoes. They were divided into two classes, fixed and moving. The fixed class are now called *submarine mines*. Reference should be made to article TORPEDO for the history of submarine mines. Submarine mines are (1) self-acting and (2) controlled, according to the conditions of firing. Self-acting or contact mines are mechanically or electrically fired. The mechanical arrangements are of numerous types, but the most common have pins or levers which are on the exterior of the case. When struck by a passing vessel the pressure, or a spring released by the lever, drives a firing pin against a fulminate primer in contact with the charge. The electrically fired are (1) simple buoyant mines anchored, like all buoyant mines, so as to be held 5 to 20 feet below the surface, and (2) combination ground mines with a buoyant contact held at a similar depth. In both these types the explosion is caused by the

completion of the circuit by driving in a pin, depressing a lever, or the operation of some other device, when the mine or contact piece is struck by a ship. Electrically fired mines usually have separate battery boxes connected by a long double conductor wire to the mine. The battery box is thrown over when the mine is launched and lies on the bottom near the anchor.

Controlled mines are (1) automatic and (2) observation. The firing wires for all controlled mines lead to mine stations. For automatic mines this is done to secure safety. When the circuit is broken at the station the channel is safe for the passage of ships, but when it is closed the mine will explode if struck. The combination controlled mine, like the combination self-acting, is a ground mine with a buoyant contact piece; it is made ready in the same manner as an automatic controlled mine. Observation mines are fired by the observers. These are placed in stations so located that their lines of sight at the mine field intersect at angles of 45° or more. Each group of mines has a corresponding contact that is passed over by the sight bar on each observer's switchboard when the sight is directed to the centre of the group. When both contacts of a group are made the mines of the group are fired; this will of course occur when a ship is directly over the group. Observation mines may be of the simple or compound buoyant type or of the ground type. The simple buoyant mine can be exploded only by the observers; the compound type has pins and levers for explosion by contact so that it may be considered as belonging also to the *automatic* buoyant controlled type. Observation ground mines are simple if fitted for explosion by the observers only, and are combination if they also have contact pieces. Drifting mines are always self-acting, and most of them are mechanically fired.

In the accompanying figures many minor details are omitted for the sake of clearness.

FIG. 1.

Figure 1 is a self-acting, mechanically fired mine, operated by the lever *b*; *a, a*, are the halves of the mine case; *c*, a detent which holds

the lever in position until struck; *d*, the transporting lug; *e*, the anchor rope. A similar mine, fitted with an electric primer and switch in place of the percussion primer and firing pin, and with electric wires connecting it to an observing station, would be an automatic controlled mine; if fitted with wires and a battery instead of connected to a station it would be a self-acting, electrically fired mine. Observation mines have a similar appearance except as regards the lever, which is omitted. Figure 2

FIG. 2.

is a self-acting, mechanically fired mine, operated by the driving in of one of the pins *k*; *l* is the shell or mine case; *m*, the transporting lug; *n*, lug for the anchor rope; *k*, *k*, *k*, *k*, firing pins. Figure 3 is one of the many types

FIG. 3.

of mine anchors; *A* is the cast-iron body; *B*, the distance weight; *C*, the distance rope; *D*, the reel carrying the anchor rope *e*; *E*, pawl to control the operation of the reel *D*; *F*, reel axle; *G*, square head of reel axle to take wrench for reeling in. Figure 4 shows the operation of

anchoring. The depth of water is assumed to be about 40 feet; the mine to be held at 10 feet below the surface. *a*, *b*, *c*, show the position of the mine in the three stages of the process. *A* is the anchor; *B*, the distance weight; *R*, the distance rope; *S*, the anchor rope. Both ropes are of soft, pliable wire. The length of the distance rope is adjusted to the submerged

FIG. 4.

distance of the mine, 10 feet. Distance weight, anchor, and mine are dropped from the mine planter when over the selected position. The distance weight (usually of lead or with a lead filling) sinks rapidly until the distance rope is fully extended; the anchor does not sink with the same speed, being of less dense material and having a cavity which has to fill with water slowly. As long as the weight of *B* hangs on the clutch *E* (Fig. 3) the reel *D* is free to turn and unreel the anchor rope, but as soon as *B* reaches the bottom the reel is locked. The weight of the anchor then drags the mine the required distance below the surface.

Mines of all the types mentioned are in common use, their various characteristics fitting them to different local conditions. Self-acting mines have the advantage of (1) being comparatively cheap, (2) can be kept in store ready for immediate use, (3) do not require specially trained men or observation mining stations, and (4) extempore mines can be easily made. But self-acting mines are all (1) rather dangerous to put out or pick up, (2) the condition of the ignition apparatus cannot be tested after the mine is placed in position, (3) they are as dangerous to friend as to foe when once placed, and (4) the contact pins and levers, for mechanical or electrical firing, may become so oxidized, rusted, or overgrown with barnacles or seaweed as to prevent their operation; this condition is quickly reached in the tropics. After being two months in the water the Spanish self-acting torpedoes (in 1898) were so overgrown with barnacles that none was in a condition to explode if struck by a ship; indeed, the United States ships struck them without causing explosion, and one mine was drawn into the propeller and hit repeated hard blows. The objections to this type are evidently such as to preclude their use in important channels where controlled mines can be placed.

Ground mines are only suitable for shallow channels. In deep water buoyant mines must always be used. They are anchored with a submergence of 5 to 20 feet below the surface and at distances apart sufficient to prevent being set off by shock from the explosion of others. For

mines filled with guncotton the extreme destructive range (according to Gen. H. L. Abbott, U. S. A.) is 14.7 feet for a 100-pound charge, 20.5 feet for a 200-pound charge, and 31.7 for a 500-pound charge. The safety interval between mines or groups should be at least eight times the extreme destructive horizontal range. Mines are now commonly filled with trinitrotoluol, which is more destructive than guncotton, but the safety range is believed to be about the same. The necessity for separating mine groups by two or three hundred feet leaves a wide interval through which a ship might pass. For this reason, and to insure her destruction in case some of the mines should fail to act, mines and mine groups are laid in several lines across the channel, the units of each line opposite the intervals in the adjacent ones. Self-acting mines are usually anchored separately, controlled mines in groups. Self-acting contact mines are frequently anchored in pairs with a line between them. If a vessel strikes the line she draws both mines alongside and explodes them.

The removal of mines is effected by sweeping or countermining. Sweeping or dragging may be effected in various ways, but is most expeditiously performed by two vessels. These steam abreast each other, a few hundred feet apart, dragging a stout wire rope, each having an end on board and the bight sliding along the bottom behind them. When one or more mines are gathered in the bight of the rope they are exploded by gunfire or a detonating charge. The operation of sweeping for mines is manifestly very dangerous unless the draft of the vessel engaged is shallow enough to pass over a mine field without hitting the mines. In the Great War of 1914 steam trawlers were much used by the British for this work, while various devices were employed in the Dardanelles, where much destruction was caused by the Turkish mines. Countermining is the explosion of mines by similar devices called countermines. Countermining is useful in clearing a narrow channel through a mine field. The countermines are laid in two or three rows along the channel to be cleared and close enough together to insure the explosion of any mines lying between them.

Modern submarine mines contain from 200 to 1000 pounds of guncotton or trinitrotoluol. Judging from the destructive force of mines in the European War a large proportion of the German mines had 500 pounds or more of explosive. When such a mine is exploded in contact with the bottom or side of a ship the result is instant destruction of the adjacent part of the hull and the sinking of the ship in a very few minutes.

The submarine mine played a very important part in this great war. It is a well-established rule of international law (q.v.) that no belligerent nation has any control of the high seas, which include all waters more than 3 miles from the coast of any nation. Notwithstanding this, the Germans strewed contact mines over a great part of the North Sea and across the ordinary trade routes. The British followed by mining another considerable area, though they defined the limits of their mines and notified neutral powers. The Germans later defined safe routes past their mines. Whether drifting mines were put out was not known. If not, then many anchored mines broke adrift. The number of neutral vessels and lives destroyed by mines

when pursuing presumably safe routes was large. In the first part of the war, up to Dec. 18, 1914, 8 Swedish vessels were sunk with a loss of life between 50 and 60; 6 Danish vessels with 6 lives; 5 Norwegian vessels with 6 lives; and 3 Netherland vessels with 15 lives. As mines are weapons of defense, the naval force acting on the offensive usually suffers most from their operation. In the last Russo-Japan War Japan lost two battleships, the Russians one. In the European War, up to March 20, 1915, the British lost by mines 3 battleships, 1 armored cruiser, 5 cruisers, 4 gunboats and torpedo vessels, 3 submarines, and 4 auxiliaries; the French, 1 battleship; the Japanese, 1 cruiser and 2 torpedo boats; the Germans, 1 armored cruiser; the Austrians, 1 cruiser and 2 torpedo boats; and the Turks, 1 gunboat.

MINE ACCIDENTS, PREVENTION OF. Mining from its nature is one of the most hazardous occupations, but the extent and degree of the dangers depend in large measure upon the precautions taken. The nature of the hazard is shown by the statement that, in 1913, 1,047,000 men were employed in coal and metal mines, and in quarries in the United States, and of this number 3651 were killed, which is at the rate of 3.49 per 1000 men employed. In 1912 the rate was 3.22 and, in 1911, 3.58. Such figures and those in the accompanying tables

DEATH RATES IN MINING VARIOUS MINERALS, UNITED STATES *

KIND OF MINES	Rate per 1000 men employed	
	1912	1913
Coal.....	3.27	3.73

properly may be studied with a graphical comparison of the death rates of coal mining in the United States and in European coal-mining countries from 1895 to 1913. This indicates that the United States death rate has been much higher in recent years than those of the other countries and shows the need of greater care in American mining.

Lessening Accidents in Metal Mines. Investigations indicate that the majority of mining accidents are caused by carelessness of one of the victims, although in many instances they are due to forgetfulness or absent-mindedness. One of the remedies is constantly to set before the miners such reminders, warnings, and safeguards that they will be led to take greater care.

Taking up the classification of accidents in the table herewith it will be observed that the largest number from any one cause in metal

CLASSIFICATION OF FATAL ACCIDENTS IN METAL MINING, UNITED STATES *

CAUSE	1913	
	Number killed	Percentage
By falls of rock or ore.....	220	32.21
By explosives.....	77	11.28
By haulage accidents.....	35	5.13
By falling.....	52	7.62
By skip or cage.....	34	4.98
By other causes.....	265	38.78
Total.....	683	100.00

* Compiled by A. H. Fay, United States Bureau of Mines.

mines is due to falls of rock from the hanging wall, or overhanging ore. A lessening of the number of such accidents can be obtained by careful inspection of the walls, barring or picking down the loose boulders, and by systematic timbering. Great improvement has been effected in some mines by employment of special inspectors, but it is inevitable that there will be some accidents from falls, though they can be materially lessened by proper care. Then, in the case of the use of explosives in metal

gether, all are prolific sources of accident. Haulage accidents are due to men being squeezed between the car and the side of the passage, to electrocution by touching the trolley wire, to the running away of a car, or a trip on a grade. These are all preventable by the use of proper safeguards.

Accidents classified "by falling" are from men falling down shafts, winzes, or steep slopes. Obviously the remedy is better ladders and landing places and the protection of edges of open areas by fences, gates, and other guards. Skip or cage accidents are generally due to bad design or arrangement, or defective workmanship, or to using worn-out or defective ropes for hoisting. Such accidents should be of the rarest occurrence. Generally speaking, greater care and more intelligent planning will eliminate many accidents classed as miscellaneous as well as those classified here.

Lessening Accidents in Coal Mining. It will be observed that by far the largest number of accidents from any one cause is from falls of roof, being about 40 per cent of the whole, and if falls from the face or pillar coal be included it makes nearly one-half of the total. Such accidents cannot be entirely prevented, but the number may be very greatly lessened by picking and barring down loose roof or coal; by systematic timbering, which consists in placing posts or timber sets at fixed intervals rather than haphazard (although the cost is greater);

CHART SHOWING FATALITIES IN MINING OPERATION.

mines, accidents from this source are due almost entirely to carelessness, forgetfulness, or improper methods. Premature firing, drilling into old charges, thawing out of frozen explosives, carelessness in handling these, dangerous magazines, and placing detonators and explosives to

better methods of testing roof, which is by the sense of touch rather than by sound, i.e., when the roof is struck with a bar or hammer, if it is loose it will vibrate, whereas whenever a large rock is struck it is difficult to judge by the sound whether the rock is loose or not. Close

MINE ACCIDENTS AND SAFETY

INVESTIGATING MINE ACCIDENTS

1. Smoke projected by an explosion from experimental mine, Bruceton, Pa.
2. Rescue party equipped with oxygen apparatus, safety and electric lamps, canary bird, and life line, entering experimental mine of United States Bureau of Mines after an explosion
3. Interior of a United States Bureau of Mines Rescue Car

MINE ACCIDENTS AND SAFETY

PREVENTING MINE EXPLOSIONS

1. Rice concentrated rock dust barrier. Appearance after successfully stopping a light pressure, slow moving explosion. The sieves have dropped and have been caught by chains, the rock dust having been distributed by the force of the explosion.
2. Reinforced concrete stopping in experimental mine, Bruceton, Pa. broken by an explosion.

and better supervision of timbering at the face is of great advantage; this is obtained by the employment of district or face bosses, so that every place can be visited several times a day. In some mines an improper system of mining is employed, which increases the hazard of dangerous falls. Excessive charges of explosive shatter

gas, chiefly methane (CH₄), is found in nearly all coal mines except those at comparatively shallow depths. Ordinarily the gas is diluted and carried away by an air current, but if the mine-ventilation arrangements are poor, accumulations of fire damp may occur, and if one of these is ignited by a flame or a spark an

* Compiled by A. H. Fay, United States Bureau of Mines.

the roof. As large charges are employed in shooting off the solid, it is of great advantage to undercut the coal either by hand or machine, thus requiring the use of smaller charges of explosive.

Accidents by haulage are due to runaway trips and cars, to catching men between the car and the side of entry, and to electrocution from touching the trolley wire. The increased use of manways, or nonhaulage roads, serves to prevent haulage accidents, as do also providing greater clearance allowance on one side of haulage ways, the placing of shelter holes at regular intervals, the guarding of trolley and feed wires by sideboards, equipping cars with better brakes, and in dipping places the careful blocking of cars. The formation of systematic rules in regard to haulage and signaling and their enforced observance will reduce the number of accidents from this cause.

Accidents from Use of Explosives other than Explosions. Practically all explosive accidents result from careless handling and distribution of explosives. The making up of cartridges of black powder with an open light on the miner's cap, careless handling of detonators, and drilling into old charges are a few of the most prolific causes. To these may be added the improper storage of explosives underground, i.e., failure to put in boxes by themselves; the detonators should always be stored separately and apart from the explosive proper.

Fire-Damp and Coal-Dust Explosions. Although the total number of deaths due to inflammation of fire damp and explosions for any one year have always been less than those due to falls of roof material, nevertheless, since individual accidents of this nature often cause the deaths of large numbers, public attention is focused by the horror of such disasters. Special attention therefore has been paid in all coal-mining countries to the investigations of explosions with the view to their prevention. There have been a great many explosions in which from 100 to 400 men have been killed at a time. The greatest explosion that ever occurred with respect to the number killed was at Courrières, France, in 1906, when 1099 men were killed.

Cause of Fire-Damp Explosions.—Inflammable

explosion may result. Explosions of fire damp are caused usually by open lights, but they may be produced by the flame of explosives and sparks or arcs from electric machinery.

Prevention of Fire-Damp Explosions.—To prevent gas explosions it is necessary, first, to cause, by means of fans, the circulation of

permissible* explosives instead of black powder and dynamite; and fourth, the use of explosion-proof motors* or the withdrawal of electric equipment from the gaseous sections of the mine.

* Officially tested by United States Bureau of Mines and approved as comparatively safe for use in gaseous and dusty mines.

Causes of Coal-Dust Explosions.—Coal dust in a pile or layer is not explosive, but when it is raised into the air in a dense cloud and is then ignited it will explode violently. Two things are therefore necessary to originate a coal-dust explosion—a means of making a dust cloud and a means of igniting it. Both conditions may be caused by a single agency, such as a blown-out shot (i.e., blast) or a small gas explosion. A blown-out shot is so called when the energy of the powder is not used in breaking the coal but blows the stemming or tamping out of the drill hole. After the first cloud of dust is ignited the pressure of the explosion may form clouds beyond, which in turn will be ignited, and the process continues, so that the explosion advances with increasing strength as long as there is fuel available.

Prevention and Stopping of Coal-Dust Explosions.—Plans for prevention comprise decreasing the amount of coal dust made in mining operations, preventing cloud formation by wetting the dust or making it noninflammable by increasing the incombustible content of the dust clouds, eliminating means of ignition by use of safety lamps and permissible explosives, and, finally, confining explosions to small areas by "barriers." The accumulation of coal dust on roads can be greatly decreased by the use of tight cars, so that the fine coal dust cannot fall out, and by loading cars only to the top of sideboards, so that the coal will not be jarred off in transit.

Wet methods of rendering coal dust inert comprise saturating the air current by steam or sprays so that it will not dry out the mine dust, and sprinkling by sprays from water cars or by pipe lines and hose. Calcium chloride and other less deliquescent salts are sometimes used on the roads to keep the road dust wet. Coal dust to be nonexplosive must be wet enough to ball in the hand.

Dry methods of preventing coal-dust explosions comprise covering all surfaces with fine incombustible rock dust artificially ground; then, if the dust is blown up into a cloud, the cloud will contain so much incombustible matter that it cannot explode, the rock dust, if that is used, absorbing heat and separating the coal-dust particles. This method has the advantage over the use of water that the latter evaporates rapidly unless the air current is nearly saturated, while the rock-dust protection remains good for long periods.

As open lights and blow-out shots of long-flame explosives are the most common igniting means of starting explosions, the replacement of them by safety and electric lamps and permissible explosives has greatly decreased the possibility of explosions occurring.

J. Taffanel, a French investigator, developed the first barrier or concentration of rock dust for stopping explosions, in case they start through failure of initial preventive means. It consisted of 10 to 15 boards placed across the mine passages just beneath the roof and loaded with rock dust. If an explosion occurred the dust was blown or upset from the shelves and quenched the flame, thus preventing the passage of the explosion to points beyond. These barriers operated successfully except in rare cases when the explosion was a slow-moving one. To take care of such cases and to protect the rock dust from wetting where wetting methods were employed, closed rock-dust barriers were de-

signed by George S. Rice, chief mining engineer of the Bureau of Mines, and tested at the Bruce-ton Experimental Mine of the United States Bureau of Mines, successfully extinguishing explosions and meeting the conditions above mentioned. The accompanying illustration shows one type; the "Concentrated Rock Dust Barrier," after extinguishing a very light explosion. It will be noted that the bottom boards have dropped, allowing the dust to sift down. In a violent explosion the whole barrier is smashed and three tons of rock dust immediately launched into the blast.

Rescue Work. Before the discovery of rescue apparatus and the development of modern methods of mine recovery rescue parties sometimes rushed into a mine after an explosion and lost their lives by suffocation from afterdamp, or by igniting gas with open lights and causing secondary explosions. In modern methods exploration is made in advance of bratticing parties by trained rescue crews equipped with the self-contained oxygen breathing apparatus, safety and electric lamps, and canaries. Such exploration hastens the discovery of any who may still be alive and insures the absence of mine fires before the restoration of the air current. The breathing apparatus is so attached to the wearer that he breathes no air or gases

CIRCULATING SYSTEM OF ONE TYPE OF RESCUE APPARATUS WITH MOUTH-BREATHING DEVICE.

from without the apparatus. It furnishes him with air having a high percentage of oxygen and constantly removes the carbon dioxide from the air exhaled by the wearer. The accompanying diagram shows the air circulation of the apparatus.

Safety lamps (q.v.) are carried by the crews to test for inflammable gas and black damp, the latter term being applied to mixtures of carbon dioxide and nitrogen. Portable electric lamps give a strong light, which is necessary for exploration work and, not using oxygen like the safety lamps, furnish illumination in any atmosphere. The actions of the canary indicate the absence or presence of small percentages of carbon monoxide (atmospheres containing only 0.25 per cent are dangerous to breathe), to which it is much more sensitive than small animals and human beings, so that if the canary is not overcome it is safe to permit men without apparatus to advance.

Many thousands of men have now been trained in the use of rescue apparatus and in rendering first aid to the injured by the United States Bureau of Mines, the State rescue stations of

Illinois, and by instructors of private stations maintained by mining companies. There are, therefore, crews in every mining district who are competent to assist in rescue work in time of disaster and alert at other times to do all in their power to prevent accidents or to furnish first aid in case of accident.

Bibliography. Sir F. A. Abel, *Mining Accidents and their Prevention* (New York, 1889); G. M. Bailes, *Modern Mining Practice* (5 vols., Sheffield, England, 1906); H. Schmerber, *La sécurité dans les mines* (Paris, 1910), containing a bibliography; J. H. Dague, *Mine Accidents and their Prevention* (Scranton, 1912); also reports, technical bulletins, and miners' circulars of the United States Bureau of Mines, available upon application or through the Government Printing Office, Washington; also official reports of Pennsylvania, Illinois, and other States.

MINE GAS. Many coal mines contain gas of an explosive nature. The most common of these is marsh gas, CH_4 , which is very explosive if mixed with the right proportions of air. This mixture is known to miners as fire damp. Other gases found in coal mines and which may be dangerous in one way or another are carbonic-acid gas, CO_2 (called black damp or choke damp), and carbon monoxide, CO (white damp). Afterdamp is a gas present after an explosion of gas in the mine and is very dangerous. On account of mine gases, miners often have to use safety lamps for illumination, these lamps being so constructed that the flame does not come in contact with the air and gas in the mine workings. The danger of explosion is also minimized by thorough ventilation. Consult bulletins issued by United States Bureau of Mines. See **COAL**; **SAFETY LAMP**.

MINEO, μέ-νά'ό. A town in the Province of Catania, Sicily, 27 miles southwest of Catania. It occupies the site of the ancient Mensa, founded by Ducetius, 459 B.C., and captured by the Saracens in 840. The ancient walls and castle are still in evidence. In the vicinity is the famous Lago de' Palici, the Lacus Palicorum, of volcanic origin with mineral springs. Pop. (commune), 1901, 9828; 1911, 8728.

MINER, ALONZO AMES (1814-95). An American Universalist minister, born at Lempster, N. H. He was educated in the public schools and after teaching for several years was ordained to the Universalist ministry in 1839 and served as pastor in Methuen, Lowell, and Boston, Mass. He was president of, and professor of ethics and political economy in, Tufts College from 1862 to 1875, when he returned to his former pastorate of the Second Universalist Church, Boston. He was appointed a member of the board of overseers of Harvard University in 1863; served 24 years (1869-93) as a member of the State Board of Education and as chairman of the board of visitors to the State Normal Art School (Boston) from 1873; was for 21 years president of the Massachusetts State Temperance Alliance; and stood as Prohibition candidate for Governor in 1878. He was the original projector of the Universalist Publishing House in Boston and became prominent in the antislavery agitation. He edited *The Star of Bethlehem*, contributed to periodicals, and published: *Bible Exercises* (1854); *Old Forts Taken* (1878); *Doctrines of Universalism*. His *Life* was published by G. H. Emerson (Boston, 1896).

MINER, CHARLES (1780-1865). An Ameri-

can journalist, born at Norwich, Conn. At 19 he removed with his family to the Wyoming valley in Pennsylvania, where he became interested in various newspapers, writing under the pen name of John Harwood. He was a member of Congress from Pennsylvania in 1825-29 and was the first to bring to the official notice of that body the possibilities of silk culture and manufacture in the United States. He returned to the Wyoming valley in 1832. The most important of his publications is a *History of Wyoming* (1845), which contains a description of the Wyoming massacre given by eyewitnesses.

MINER, THOMAS (1777-1841). An American physician, born at Middletown, Conn. After graduating from Yale in 1796, he then taught school and studied law, but turned to medicine and established himself in practice at Lynn, Mass. He was one of the founders of the Yale Medical School and was president of the Connecticut State Medical Society from 1834 to 1837. He is the author of *Essays upon Fevers and Other Medical Subjects* (1823), with Dr. William Tally, and *Typhus Syncoptalis . . . or the Spotted Fever, etc.* (1825).

MINERAL ACID, IN MEDICINE. An acid not of animal or vegetable origin. The mineral acids most generally used in medicine are sulphuric (oil of vitriol), nitric (aqua fortis), hydrochloric (muriatic), nitrohydrochloric, and phosphoric. In their medicinal action they have many properties in common.

The strong acids are escharotic, abstracting the waters of the tissues, combining with the albumin and other bases, and destroying the protoplasm. They are very diffusible. Sulphuric and phosphoric acid have a strong affinity for water, completely decomposing tissues to which they are applied; they are therefore powerfully escharotic. Sulphuric acid makes a black eschar, while nitric and hydrochloric acid turn the tissues yellow. They are all astringent to the tissues, hydrochloric being the weakest and sulphuric the strongest in this respect.

These acids diluted produce a peculiar metallic taste in the mouth and a sensation of roughness on the teeth. They stimulate the flow of saliva from the parotid and submaxillary glands. They promote the alkaline secretions of the intestines and of glandular organs (bile, etc.); but check the secretions of acid fluids, as the gastric juice. Given before meals, in small doses, they relieve undue acidity of the stomach by checking the production of the acid gastric juice. At first they aid digestion, being helpful to the action of pepsin; combined with stomachics they are useful in dyspepsia with deficiency of the gastric juice. If continued too long they may impair digestion by lessening the production of the gastric juice. They check fermentation and constipate the bowels, except nitric acid, which relaxes them.

Antidotes for poisoning by these acids are: alkalis, such as bicarbonate of soda, lime water; or in an emergency plaster from a wall may be mixed with water to neutralize the acid; oil, albumin, and milk to protect the mucous membranes. For stimulants, opium and ammonia (intravenously) may be used to counteract the resulting depression of the vital powers. See **ANTIDOTE**.

All these mineral acids, if well diluted, are classed as refrigerants and are useful in fevers, especially in typhoid. Hydrochloric is here preferable. Nitric is the acid generally preferred

as a caustic, its action being effectual and superficial; it may be applied undiluted to phagedenic ulcers and sloughs, warty growths, and indolent sores. Sulphuric acid, dilute, is appropriate in cases of diarrhoea, colliquative sweating, and as a prophylactic against lead poisoning; it is used also as an acid drink in fevers and before meals in acidity of the stomach. Phosphoric acid is considered of special value in tissue waste and in dissolving phosphatic deposits. All these acids act injuriously on the teeth by attacking the enamel. They should always be administered largely diluted, taken through a straw or glass tube, and the mouth should be thoroughly rinsed at once with an alkaline wash. See NITRIC ACID; HYDROCHLORIC ACID.

MINERAL COLORS. A term applied to a number of inorganic substances used in the manufacture of paints. The principal mineral colors include the following: *white lead*, consisting chiefly of basic lead carbonate; *zinc white*, or oxide of zinc; *antimony white*, or oxide of antimony; *fixed white* (*blanc fixe*), artificial or natural barytes, barium sulphate; *mineral white*, or calcium sulphate; *china clay*, or aluminium silicate; *whiting*, or calcium carbonate; native or artificial *yellow ochres*, i.e., earths colored by iron oxide; *litharge*, *massicot*, or oxide of lead; *strontian yellow*, or chromate of strontium; the chromates of cadmium, mercury, and barium; *mineral yellow*, or oxychloride of lead; *Naples yellow*, or antimonate of lead; *orpiment*, or sulphide of arsenic; *rouge*, Venetian and Indian reds or red oxides of iron; *vermilion* and *cinnabar*, or sulphide of mercury; *Derby red*, or basic chromate of lead; *minium*, or orange mineral (red lead), or lead orthoplumbates; *realgar*, or red sulphide of arsenic; *Brunswick green*, or oxychloride of copper; *Scheele's green*, or copper arsenite; *Schweinfurt green*, a mixture of copper acetate and Scheele's green; *cobalt green*, or cobalt and zinc oxide; *umber*, or brown silicate of iron and manganese; native or artificial *brown ochres*, i.e., earths colored by iron oxide; *Berlin blue*, or ferrocyanide of iron; *Thénard's blue*, or aluminate of cobalt; *ultramarine blue*, a compound of aluminium, sodium, silicon, oxygen, and sulphur; etc. The principal mineral colors are described in special articles or in connection with the metals or acids combined in them. See also PAINTS; PAINTERS' COLORS.

MINERAL DEPOSITS. See ORE DEPOSITS; and the articles on the different ores and minerals.

MINERALOGY (by hapology for **mineralogy*, from *mineral*, OF. *minéral*, Fr. *minéral*, from ML. *minerall*, ore, from *minera*, *mineria*, *minaria*, mine, from *minerarius*, pertaining to mines, from *minare*, to mine, lead here and there, Lat. to drive, from *minari*, to threaten, from *mina*, threats, from *minere*, to jut out + *-λογία*, *-logia*, account, from *λέγειν*, *legein*, to say). The science of those natural substances known as minerals which, together or separately, form the material of the earth's crust and also, as far as our knowledge extends, that of other celestial bodies. A mineral is a substance of definite chemical composition which has been directly produced by the processes of inorganic nature. It must be homogeneous even when submitted to minute microscopic examination and must possess a definite composition capable of being expressed by a chemical formula. Laboratory and

furnace products, or such substances as shells and bones of animals, cannot be included in the range of mineralogy. It is the function of the mineralogist to investigate the form, properties, and composition of minerals, their genesis, their relations to one another and to the accompanying rocks, the places where they are found, and the geological conditions under which they are formed. A knowledge of mineralogy is of importance to the geologist in his study of the rock formations, to the mining engineer in his search for metal-producing minerals, and to the metallurgist in the extraction of metals from minerals. Many of the useful arts are directly dependent for their raw materials upon minerals, while some mineral species occur in such brilliancy and beauty of color as to be highly prized as gems.

The Branches of Mineralogy. The general subject of mineralogy may be divided into four sections: 1. *Crystallography*, which includes the description of crystals, their character, classification, the mathematical relations of their faces, and the methods of expressing them graphically and symbolically. (See CRYSTALLOGRAPHY.) 2. *Physical mineralogy*, which describes the physical characters of minerals and deals with the properties related to their molecular structure. 3. *Chemical mineralogy*, which has for its object the determination of the chemical composition of each mineral species and the relation in composition between species in the same chemical group. 4. *Descriptive mineralogy*, which includes the detailed description of each mineral species with respect to its form, structure, physical properties, chemical composition, and geographical and geological occurrence. The division of physical mineralogy is replete with interesting problems of cohesion, optics, heat, and electricity, and suggests to the investigator along physical lines many fields for research. The problems connected with chemical mineralogy, while covering a narrower and less varied field than those of physical mineralogy, are none the less replete with interest. To the chemist working in the field of mineralogy belongs the task of determining the part played by the various elements which enter into the composition of the hundreds of mineral species, many of which are rare and exceedingly complex in composition; the phenomena of isomorphism and dimorphism; and the chemical alteration of mineral species under the action of natural agencies, which is known as pseudomorphism.

Crystallography. With very few exceptions (mercury and water) minerals are limited to solid substances; i.e., they are solid at the present temperature of the earth. In discussing their formation and character we must, however, revert to the period when the mineral constituents of the earth existed in a fluid or semi-fluid state. When a homogeneous substance passes from a fluid to a solid condition, its particles mutually attract each other along certain definite lines and a solid is built up which shows a definite structural relation between all its integral parts, which relation finds expression in its outward form. Such a solid, formed from a nucleus by the piling up of accretions from without, is known as a crystal and is characterized by a regular polyhedral form, bounded by more or less smooth surfaces. A crystal is, then, the normal form of a mineral which has solidified under ideal conditions and, should its formation be uninterrupted by external agencies, its ap-

1. Normal crystal form developed equally in all directions.
 2. Same crystal form as 1, distorted.
 3. Crystal molecule showing an arrangement of attractive and repellant forces.

4. Network of molecules formed on the lines of crystallizing forces shown in 3.
 5. Further development of network shown in 4 to explain cleavage.
 6. Twin crystal formed by two interpenetrated cubes.

pearance would be that of a symmetrical geometric solid with smooth faces and sharp edges and angles. Such are the ideal representations, which serve to illustrate the crystallization of mineral species and which are to be found in all textbooks on the subject. But inasmuch as the ideal conditions mentioned above are of comparatively rare occurrence, it is far more common to find minerals in more or less distorted forms. (See Figs. 1 and 2.) Large and well-formed crystals are, in general, produced by a slow process of crystallization, whereas a rapid cooling or concentration of a mineralizing solution tends to form aggregates often resembling the forms of animate nature; such are the frost patterns which form on windowpanes, the coral-like forms of calcium carbonate to be found in some caves, and many other imitative forms described in the terminology of mineralogy. Where individual crystals are entirely lacking, the mineral is said to be massive, although its structure as determined by optical and other methods may be distinctly crystalline.

Regarding the nature of the crystalline units of accretion, there is at present very little knowledge. They are without doubt extremely minute and may possibly consist of a number of chemical molecules. Whatever may be the size or shape of the crystal units or crystal molecules, it is sufficient for the purpose of discussion to regard them as points. A fuller discussion of this subject will be found under CHEMISTRY. The crystal molecules of any chemical substance crystallizing under given conditions are believed to be identical in size and shape. They are never in contact with each other, but are held in equilibrium by attractive and repulsive forces acting along lines which differ for each type of crystal molecule. A crystal molecule having these lines of crystallizing force at right angles, as shown in Fig. 3, would attract like molecules, which would arrange themselves as shown in Fig. 4. The theoretical grouping of molecules has been discussed by Sohncke, Fedorow, Schönflies, and Barlow, who have developed 230 possible groupings. These, however, divide themselves into 32 distinct groups identical with the 32 groups mentioned under CRYSTALLOGRAPHY.

If we assume the molecules of a substance to be grouped as shown in Fig. 5, it will be readily seen that the lines of minimum cohesion will be *aa* and *bb* rather than *mm*, because the former planes are further separated from the next adjacent parallel plane. This explains in a measure the fact that crystallized substances often tend to break or cleave parallel to a primary crystallographic face. Assuming a crystal molecule of any given mineral to be held in equilibrium by forces acting in definite directions, it will be readily seen that the crystal built up from accretions of such molecules will, of necessity, present faces which are symmetrically disposed with respect to those lines of crystallizing force. Thus, we have as a fundamental law of crystallization the principle that a mineral can crystallize only in forms whose symmetry is referable to one of the 32 groups mentioned in the foregoing paragraph. This is known as the law of symmetry. The number of planes possible from the grouping together of crystal molecules of a substance is invariably greater than the number occurring on any given crystal, and modifying planes are common, often running to great complexity and under unusual

conditions predominating over the commoner types. Hence we frequently find great variety of form in crystals of the same substance, as is the case with the mineral calcite (q.v.). It should, however, be noted that crystals of a mineral from a certain locality, which are presumably formed under the same conditions, show a marked similarity of type and are readily distinguishable from those of the same mineral from a different locality. This variation in type, which is known as crystal habit, is particularly noticeable in large and widely distributed species. Certain mineral species exhibit a tendency to join two crystals or two halves of the same crystal in such a manner that some crystallographic plane or axis is common to both. This juxtaposition, which is ordinarily distinguished by reëntering angles, is known as twinning. (See Fig. 6.)

It will be readily seen from the above that an accurate knowledge of the occurring crystal forms is of primary importance in the investigation of any mineral species. The identification of the faces of the crystal, which is often attended with considerable difficulty, is accomplished by measuring the interfacial angles by means of an instrument called a goniometer (q.v.) and comparing these with the calculated relations obtained from simple mathematical formulas based on spherical trigonometry. The optical properties of minerals as well as their presence and relations in rocks are determined by means of the petrographic microscope. (See MICROSCOPE.) For exhaustive study along the line of physical characters, elaborate and accurate apparatus is required, while a well-equipped chemical laboratory is almost indispensable to the mineralogical investigator.

Minerals and Rocks. One of the most important phases of mineralogical study, and one which is replete with interest to the geologist, is the relation of minerals to rocks. The division known as the crystalline rocks, in particular, presents a wide and varied series of rock-forming minerals. These may be classed as essential and accessory constituents according as they give character in the rock in which they occur or are present only in insignificant proportions. Quartz, the feldspars, the micas, hornblende, augite, enstatite, hypersthene, chrysolite, garnet, leucite, serpentine, calcite, and dolomite are essential constituents of many crystalline rocks, while such minerals as gypsum, salt, limonite, hematite, siderite, kaolin, magnetite, and apatite often occur in such extensive deposits as to constitute rock masses. Among the accessory rock-forming minerals may be mentioned graphite, corundum, vesuvianite, chialstolite, cyanite, tourmaline, zircon, titanite, etc. Many geologists have made use of the mineralogical character of rocks as a basis of classification, particularly in the case of the igneous rocks, and, though open to some objection from the standpoint of geological inquiry, the system as applied to crystalline rocks has much to commend it.

Mineral Chemistry. Comparatively few elements exist in nature uncombined; the great majority of minerals occur as salts of relatively few mineral acids. Minerals crystallizing from a mineralizing fluid, whether it be a solution or a fusion, combine the elements existing in that fluid in strict accordance with the laws of chemistry. The resulting minerals may, however, be somewhat modified by the presence of elements foreign to their typical formulas, as in the case

of the emerald variety of beryl, which owes its brilliant green color to the presence of a small amount of chromium not represented in the normal composition of beryl. Again, certain elements closely related in chemical character frequently replace one another in mineral composition, the relative proportions varying between limits and giving rise to a group of closely related compounds. Such is the columbite-tantalite group, which presents all the gradations from normal columbite (FeNb_2O_6) to normal tantalite (FeTa_2O_6). Minerals closely related in composition often exhibit a striking similarity in crystal form. When such isomorphous compounds are present in the same magma they are not separable in the process of crystallization, but tend to produce a mineral intermediate in composition, as when the isomorphous carbonates dolomite and siderite grade into the intermediate compound ankerite. An extremely interesting group is that of the triclinic feldspars or plagioclases, which are regarded as isomorphous mixtures of the molecules of the two isomorphous species albite and anorthite. Mineralogy affords several examples of mineral species identical in chemical composition, but crystallizing in forms which are essentially different. This condition, which is known as dimorphism, is represented by the two calcium carbonates calcite and aragonite and by the two iron disulphides pyrite and marcasite. Titanium dioxide, which is trimorphous, occurs as rutile, octahedrite, and brookite.

Classification of Minerals. The most logical and convenient scheme of classification of minerals is that which is adopted by Dana in his *System of Mineralogy* and which is now, with slight modifications, universally used. By this method mineral species of similar composition are placed together in classes which are subdivided into divisions. These in turn are split up as far as possible into isomorphous groups. The principal classes are:

1. Native elements.
2. Sulphides—sulphides, selenides, tellurides, arsenides, and antimonides.
3. Sulpho salts—sulpharsenides, sulphantimonides, and sulphobismuthites.
4. Haloids—chlorides, bromides, iodides, and fluorides.
5. Oxides.
6. Oxygen salts—carbonates, silicates, and titanates; niobates and tantalates; phosphates, etc.; borates and uranates; sulphates, etc.; tungstates, molybdates.
7. Salts of the organic acids.
8. Hydrocarbons.

Uses of Minerals. By far the most important of the uses to which minerals are put is that of producing metals from those of them which contain metal constituents in sufficient quantity to render their mining profitable. The discussion of the distribution and mode of occurrence of metallic ores involves many questions of a purely technical nature and belongs essentially to the province of ore deposits (q.v.). A few metals such as gold, platinum, copper, arsenic, and to some extent silver, antimony, bismuth, and mercury, are found native, i.e., uncombined with other elements. The majority of the metallic ores, however, occur as sulphides, oxides, or carbonates of the various metals, or more rarely as arsenides, tellurides, chlorides, or silicates. Association of metallic minerals in more or less intimate mixtures often gives rise

to highly complex ores. Many ores which are essentially compounds of the base metals contain gold and silver in appreciable amounts and are profitably mined for the latter metals, as is the case with the argentiferous galena of Colorado, Montana, and Utah.

The nonmetallic minerals, although of less importance commercially than the metallic ores, are none the less of great and increasing value in the arts. These are grouped, with reference to their application, into: 1. Substances used for chemical purposes, embracing the minerals employed in the manufacture of acids, chemicals, soda, alum, plaster of Paris, etc. 2. Ceramic materials, used in making pottery, bricks, tiling, paving blocks, terra cotta, porcelain, and glass. 3. Refractory materials, used in the manufacture of fireproofing, linings of furnaces, crucibles, and asbestos fabrics. 4. Abrasives, embracing diamonds, emery, garnet, and quartz sand. 5. Graphic materials, embracing chalk, graphite, pencil stone, lithographic limestone, etc. 6. Pigments, including minerals ground for paints, and paint adulterants. 7. Fertilizers, represented by the lime phosphates, marls, and land plaster. 8. Mineral fuels, including coal, petroleum, and natural gas. The use of certain minerals for gems is probably of very ancient origin. The extreme hardness of the diamond, sapphire, ruby, emerald, chrysoberyl, and other precious stones protects them from injury and renders them capable of being highly polished.

Synthetic Mineralogy. Almost all of the important minerals have been successfully produced artificially, and much light has been thrown upon the formation of natural minerals in this way. The methods applied to this line of research involve in the majority of cases a fusion at a high heat for a long period. In a number of instances artificial minerals have been accidentally produced in the course of various metallurgical operations, and the interiors of retorts and furnaces often furnish interesting examples of this phase of mineral genesis. In point of economic importance these experiments, though interesting, have not as yet achieved a marked degree of success in the production of gems, except in the case of the corundum gems, which are now manufactured and sold as synthetic sapphires.

Analysis of Minerals. The determination of minerals is largely a question of experience gained by the study of large and varied collections of specimens. The eye becomes trained by practice to recognize crystallizations even in distorted and imperfectly exposed forms, to associate certain colors, lustre, and structure with definite species, and to associate certain minerals with certain rock matrix. Several physical properties are of considerable aid in identifying questionable specimens, as, e.g., the color of the powdered mineral as shown by rubbing it on unglazed porcelain, the approximate relative hardness as determined by scratching the specimen with a knife point, and the relative weight as roughly determined by weighing the specimen in the hand. These rough determinations, which are of particular value as field methods, may be supplemented, with the addition of some simple and portable apparatus, by determinations of solubility and fusibility. A more detailed examination of the composition of a mineral involves recourse to the blowpipe analysis. Blowpipe analysis, as it is at present

practiced, consists of a quantitative chemical analysis on a small scale. For this purpose very small portions of the substance to be examined are used, and most of the chemical reactions involved are effected by means of some form of blowpipe (q.v.). Formerly the methods of blowpipe analysis were extended and elaborated to include quantitative determinations, but the smallness of the samples which could be successfully treated rendered the results of quantitative blowpipe analysis inexact, even when practiced by a skilled and experienced manipulator, and this branch has now been abandoned in favor of the more reliable methods of quantitative analysis (q.v.). Some idea of the results obtained by blowpipe analysis will be gained by an examination of the accompanying plate, which shows the reactions obtained from some of the fusible metals by heating their compounds with suitable fluxes on charcoal and plaster supports. The coatings of iodides are produced by using a flux composed of two parts sulphur and one part each of potassium bisulphate and potassic iodide. Reactions for iron, copper, manganese, nickel, cobalt, chromium, and other metals are obtained by dissolving small portions of their compounds in hot beads of borax or microcosmic salt and subjecting the resulting fusion to the oxidizing and reducing action of the blowpipe flame. The color imparted to the blowpipe flame serves as a test for compounds of calcium, strontium, lithium, barium, sodium, and other elements. These tests as well as others of similar nature merely announce the presence or absence of an element; the relative amount when required must be determined by a systematic quantitative analysis.

History. Although a few mineral species were known to philosophers at an early date in the world's history, it was not until the development of chemistry from alchemy in the sixteenth century that savants approached the subject of mineralogical knowledge in the true spirit of scientific investigation. As a natural outcome of the comparatively advanced state of mathematical knowledge at the period of this scientific awakening, the subject of crystallization early developed a marked importance. In 1783 Delisle, with the aid of a primitive form of goniometer, measured the interfacial angles of a number of crystals and established the law of constancy of interfacial angles. The Abbé Haüy about the same time developed a theory correlating the internal structure of crystals with their outward form. He practically formulated the law of rational indices which constitutes the corner stone of crystallography. Haüy was followed by Hausmann with his application of spherical trigonometry in 1803, Weiss with a development along purely mathematical lines in 1814, Mohs with a division of crystals into six systems in 1822, Naumann in 1823, and W. H. Miller in 1839. In recent years the science has made vast strides, and new methods and lines of research are being constantly developed. Our knowledge of the science of mineralogy is constantly enriched by the discovery of new species, while mining and quarrying operations are continually bringing to light new and interesting crystalline forms and varieties of well-known minerals.

Research in physical mineralogy is being extended, notably in Germany, along a number of lines, and from time to time valuable additions

are made to our store of knowledge by careful and exhaustive studies of the optical, thermal, and electrical properties of certain mineral species. A method by which the symmetry of crystallized minerals may be investigated has been developed by Baumhauer, Beck, and others. This method depends upon the development of minute angular cavities upon crystal faces by means of the interrupted action of some dissolving medium. The symmetry of these pits, which are known as etch figures, conforms to the crystallographic symmetry of the mineral experimented upon. Of a similar nature in their bearing upon the question of crystal structure are the percussion figures and solution planes which have been made objects of special study by several authors.

The artificial formation of minerals opens another line of research upon which much valuable work has been done by Daubrée, Fouqué, Michel Lévy, Friedel, Bourgeois, Meunier, and others.

Bibliography. Among valuable works on general mineralogy may be mentioned: Des Cloizeaux, *Manuel de minéralogie*, with atlas (Paris, vol. i, 1862; vol. ii, part i, 1874); Hillary Bauerman, *Text-Book of Descriptive Mineralogy* (London, 1884); Tschermak, *Lehrbuch der Mineralogie* (Vienna, 1885); Hintze, *Handbuch der Mineralogie* (Leipzig, vol. ii, 1897; vol. i, 1902-04); the invaluable *International Catalogue of Scientific Literature: Mineralogy* (London, 1901 et seq.); E. S. Dana, *Text-Book of Mineralogy* (new enlarged ed., New York, 1910); J. D. Dana, *System of Mineralogy* (6th ed., with Appendices 1, 2, ib., 1911). Of a rather more elementary nature, but of considerable value to the student of mineralogy are: E. S. Dana, *Minerals and How to Study Them* (2d rev. ed., New York, 1897); Moses and Parsons, *Mineralogy, Crystallography, and Blowpipe Analysis* (4th ed., ib., 1909); Phillips, *Mineralogy* (ib., 1912).

In addition to the above the following works are especially devoted to crystallography and physical mineralogy: Mallard, *Traité de cristallographie géométrique et physique* (Paris, vol. i, 1879; vol. ii, 1884); Liebisch, *Geometrische Krystallographie* (Leipzig, 1881); Story-Maskelyne, *Crystallography: The Morphology of Crystals* (London, 1895); G. H. Williams, *Elements of Crystallography* (New York, 1891); Groth, *Physikalische Krystallographie* (Leipzig, 1894-95); A. J. Moses, *Character of Crystals* (New York, 1899); Hillary Hilton, *Mathematical Crystallography* (Oxford, 1903).

Valuable textbooks on determinative mineralogy are: Endlich, *Manual of Qualitative Blowpipe Analysis* (New York, 1892); G. J. Brush, *Manual of Determinative Mineralogy* (16th ed., ib., 1903).

Of value in the study of minerals in rock sections are: Rosenbusch, *Mikroskopische Physiographie der petrographisch wichtigen Mineralien* (Stuttgart, 1873; 3d ed., 1892; trans. and abridged by Iddings, New York, 1888); L. M. Luquer, *Minerals in Rock Sections* (3d ed., New York, 1908).

The following works are useful for reference on subjects connected with economic mineralogy: F. P. Dewey, *Preliminary Descriptive Catalogue of the Systematic Collections in Economic Geology and Metallurgy in the United States National Museum*, Bulletin 42, United States National Museum (Washington, 1891); J. A. Roush,

The Mineral Industry (New York, annually, 1892 et seq.); G. P. Merrill, *The Non-Metallic Minerals: Their Occurrence and Uses* (2d ed., ib., 1910).

In addition to these the reader is referred to the volumes on *Mineral Resources of the United States*, published by the United States Geological Survey (Washington, 1882 et seq.).

MINERAL PAINT. See PAINT, MINERAL.

MINERAL POINT. A city in Iowa Co., Wis., 50 miles west of Madison, the State capital, on the Chicago, Milwaukee, and St. Paul and the Mineral Point and Northern railroads (Map: Wisconsin, C 6). It contains an attractive high-school building, a public library, and a municipal auditorium. The chief industry is the manufacture of oxide of zinc, lead and zinc both being found in the vicinity. The water works are owned by the city. Pop., 1900, 2991; 1910, 2925.

MINERAL TALLOW, or HATCHETTITE. A yellowish-white, soft, flexible mineral wax or tallow that melts at 46° or 47° C. and consists of about 86 per cent of carbon and 14 per cent of hydrogen. It is found in the coal measures in Glamorganshire, Wales; Argyleshire, Scotland; and Moravia, Austria. See OZOCERITE.

MINERAL WATERS. The term usually applied to spring or well waters which have a variable quantity of solid substances in solution, and on this account may exert effects on the human body different from those of ordinary water. Mineral waters have been used as remedial agents from a very early period. The oldest Greek physicians had great faith in their curative power, and the temples erected to Æsculapius were usually close to mineral springs. We are indebted to the Romans for the discovery not only of the thermal springs in Italy, but also of some of the most important springs in other parts of Europe, as those of Aix-la-Chapelle, Baden-Baden, Bath, and Spa in Belgium. In the United States mineral springs have also attracted attention since an early period. At Saratoga Springs, e.g., the High Rock Spring was known to the white people as early as 1767, and the American aborigines seem to have been acquainted with its important properties even before that date. In West Virginia and Virginia seven springs were already noted in 1831, and of these the Bath mineral spring, now known as the Berkeley Spring, was visited as early as 1777, while the White Sulphur Springs were utilized in 1778. The therapeutic action of mineral waters or spas, as they are frequently termed, depends largely on their chemical composition and their temperature, although a variety of other circumstances, such as situation, elevation, climate, mean temperature and, above all, the regular habits of the patient, have no doubt an important bearing on the success of the treatment.

Origin. The origin of mineral waters is often looked upon with much curiosity, and yet there is nothing unnatural about it. The rain water falling on the surface soaks down through the soil into the rocks and may slowly filter through them to a considerable depth, coming out to the surface at a lower level in the form of a spring; or again the water may reach sufficient depths to be subjected to great pressure or even heat, and coming to a fissure or being struck by an artesian-well boring, it will tend to escape to the surface through such an outlet. Many mineral springs are found along lines of faulting,

since fault fissures afford a means of escape. The dissolved mineral substances no doubt are obtained from the rocks through which the water has flowed. In some cases the waters in seeping through one type of rock may take up certain acids which later react on basic elements contained in other rocks, thus producing salts. Most waters contain some carbonic acid, which greatly increases their solvent powers in the presence of lime, magnesia, and iron; while, if the waters are alkaline, they may take up substances which are ordinarily rather insoluble, such as silica. The attacking power of the water may be still further increased if it is hot. There seems to be some relation between hot springs and the geological structure of a region, as thermal springs are more abundant in areas where the rocks have been highly faulted or where there has been volcanic activity in comparatively recent geological times. Mineral springs commonly contain more dissolved material in regions of sedimentary rock formation than in igneous or metamorphic areas.

Temperature. Springs are commonly characterized as thermal when they have a temperature of over 70° F. If the temperature is between 70° and 98°, they are called tepid, while all exceeding the latter limit are included under hot springs. The following examples will serve to show the degrees of temperature found in different thermal springs: Sweet Springs, W. Va., 74° F.; Warm Springs, French Broad River, Tenn., 95°; Washita, Ark., 140°-156°; San Bernardino Hot Springs, Cal., 108°-172°; Las Vegas, N. Mex., 110°-140°; Sulphur Springs, Aix-les-Bains, France, 108°; Kaiserquelle, Aix-la-Chapelle, Prussia, 131°; Karlsbad (Sprudel), Bohemia, 162°.

Flow of Springs. The amount of water which a mineral spring may discharge is quite variable; thus, 500 springs in central France, which were tested, yielded 2,628,000 gallons in 24 hours, and the famous Orange Spring in Florida is said to discharge 5,000,000 gallons per hour. The discharge per hour of some of the principal American springs is as follows: Champion Springs, Saratoga, 2500 gallons; Roanoke Red Sulphur Springs, Va., 1278 gallons; Warm Sulphur Springs, Bath, Va., 350,000 gallons; Hot Springs, Ark., 20,100 gallons; Glen Springs, Waukesha, Wis., 45,000 gallons; Horeb, Waukesha, Wis., 1500 gallons.

Classification. A classification of mineral waters may be geographic, geologic, therapeutic, or chemical. The following scheme of classification is one adopted by A. C. Peale, a noted authority on the subject of mineral waters, and more especially those of the United States:

CLASSIFICATION OF MINERAL WATERS

Alkaline			
Alkaline-saline	{ Sulphated Muriated	{ Sodio Lithio Potassio Calcio Magnesio Chalybeate Aluminous	{ Nongaseous Carbonated Sulphurated Asotiated Carbonated
Saline	{ Sulphated Muriated		
Acid	{ Sulphated Muriated Silicious	{ Sulphated Muriated	

The alkaline waters include all those containing alkaline carbonates, such as carbonates of

alkalics, alkaline earths, alkaline metals, or iron. About one-half of the alkaline springs of the United States are calcic alkaline, i.e., containing calcium carbonates or bicarbonates as the predominant ingredient. The water of the Hot Springs of Virginia is a hot, carbonated, calcic alkaline water. The *alkaline-saline* waters include those containing combinations of alkaline carbonates with sulphides (sulphated) or chlorides (muriated), there being in the United States one-third as many as of the saline waters. In the *saline* waters sulphides and chlorides predominate; in the United States there are about one-third more springs of this class than of the alkaline springs. Springs which are classified as purgative or aperient will fall in the subclass of sulphated salines. The salines may be sodic sulphated or muriated, or calcic sulphated or muriated; the sodic muriated constitute about 88 per cent of the muriated saline waters of the United States. The *acid* class includes all waters containing free acid, whether silicic, sulphuric, or hydrochloric. In addition to having free acid a spring may also contain salts of the acid.

Geographical Distribution. There are at the present time probably not less than 10,000 mineral springs in the United States, and of this number 838 were listed as commercial producers in 1913. Most of the mineral springs of commercial value are found in the eastern United

waters are effectual in diseases of the liver, spleen, and skin, in neuralgia, and rheumatic and dyspeptic troubles. Farther south in the Appalachians are the celebrated Hot Springs of Virginia, including the Berkeley Springs and the White Sulphur Springs. The waters of the former are used chiefly for certain forms of dyspepsia, diseases of the liver and bowels, while those of the latter are of special value in the treatment of chronic diseases, gout, rheumatism, etc. The general character of the springs of Virginia and West Virginia is saline; sulphureted waters are the most numerous, but alkaline and chalybeate and acid springs also occur. The saline springs are found in excess of all others in the South Central States, and thermal springs are few. In this region the States of Kentucky, Tennessee, and Arkansas are the chief producers of mineral waters. The Hot Springs of Arkansas are among the most important thermal springs found in the entire country and are of value for diseases of the blood. The Texas springs are peculiar from the fact that many of them show free sulphuric acid. Owing to the abundance of limestone formations in the North Central States, calcic springs are quite numerous, and in Wisconsin those of Waukesha are widely known. In the Cordilleran region the most noted occurrence of hot springs is that of the Yellowstone Park, but they are not used for medicinal purposes. In New Mexico the Las

States and in the Mississippi valley; west of the 101st meridian they are largely confined to the Pacific coast. No hot springs are known in the New England States. In Maine the springs are slightly alkaline-saline and chalybeated, with a few of carbonic character. Their temperature ranges from 40° to 46° F. Chalybeated springs are abundant in Massachusetts. Many of the springs of the New England States are utilized for commercial purposes, but among the Eastern States as a whole New York stands at the head of the list of producers. The springs at Saratoga have an international reputation and compare favorably with any of the foreign spas; they attract great numbers of tourists and health seekers, and their waters are extensively used throughout the United States. These

Vegas Hot Springs are often visited, and in Washington the Medical Lake is the source of one of the best-known mineral waters of the Pacific coast.

Foreign Waters. A number of foreign mineral waters are imported into the United States and find a considerable sale. Chief among these is the Apollinaris water, which comes from Ahrweiler, Germany, and which is largely used as a table water and in cases of nervous irritation attended with dyspepsia. The Friedrichshall bitterwater, from the Friedrichshall Springs, near Hildenburg, Germany, is largely used for habitual constipation, as is the Hunyadi-János water from Budapest, Hungary, which is a remedy also for congestive and gouty disorders. The Kissingen waters from Bavaria, the Vichy

from France, and the Karlsbad Sprudel waters are extensively imported into the United States.

Production. The production of mineral waters in the United States in 1913 amounted to 57,867,399 gallons, valued at \$5,631,391. The imports in the same year amounted to 3,364,676 gallons, valued at \$955,788.

Chemical Analyses. The table on page 725 shows the important constituents of some of the American mineral waters.

Bibliography. Peale, "Lists and Analyses of the Mineral Springs of the United States," in *United States Geological Survey, Bulletin No. 32* (Washington, 1886); Branner, "Mineral Waters of Arkansas," in *Arkansas Geological Survey Report* (Little Rock, 1891); Schweitzer, "A Report on the Mineral Waters of Missouri," in *Missouri Geological Survey, vol. iii* (Jefferson City, 1892); Peale, "Natural Mineral Waters of the United States," in *United States Geological Survey, Nineteenth Annual Report* (Washington, 1898); Crook, *Mineral Waters of the United States and their Therapeutic Uses* (Philadelphia, 1899); De Launay, *Recherche, captage et aménagement des sources thermominérales, origine des eaux minérales, géologie, propriétés physiques et chimiques* (Paris, 1899); Bailey, "Mineral Waters of Kansas," in *Kansas Geological Survey, vol. vii* (Topeka, 1902); Kemp, "The Mineral Springs of Saratoga, N. Y.," in *New York State Museum, Bulletin 159* (1912). For statistics of production, see *Mineral Resources*, issued by the United States Geological Survey (Washington, annually); many references also in the volume for 1913. See BOTTLING AND BOTTLING MACHINERY.

MINERAL WELLS. A city in Palo Pinto Co., Tex., 55 miles by rail northwest of Fort Worth, on the Weatherford, Mineral Wells, and Northwestern and the Gulf, Texas, and Western railroads (Map: Texas, C 3). It is essentially a health resort, owing to its noted mineral wells, and attracts thousands of visitors annually. More than 1,000,000 gallons of the water are bottled and shipped from here every year, and the drinking pavilions of the city are said to be among the largest in the country. Places of interest in the vicinity are Lake Pinto, Elmhurst Park, and Lovers' Retreat, all of great scenic beauty. Mineral Wells adopted the commission form of government in 1913. Pop., 1900, 2048; 1910, 3950.

MINERS, WESTERN FEDERATION OF. A centralized association of persons working in and around mines, mills, and smelters. Its purposes are the general improvement in the conditions of labor and the abolition of such abuses as the truck system, child labor, the employment of private detectives, importation of labor under contract, government by injunction, etc. The officers of the association consist of a president, vice president, secretary treasurer, and an executive board composed of these officers and one organizer from each of the six districts into which the territory covered by the Federation is divided. The executive board acts as a board of conciliation and arbitration (which are strongly recommended by the Federation), may levy assessments in case of emergency, must approve every strike and joint contract entered into by local unions, and between the annual conventions has full power to direct the workings of the Federation. The Western Federation of Miners officially indorses Socialism and advocates participation of labor organizations in politics with

the view of securing to the working classes the ownership and operation of the means of production. It was founded May 15, 1893, largely as an outcome of the notorious Cœur d'Alène strike of 1892. In April, 1899, it again became involved in the Cœur d'Alène strike of that year, and in the later period of the strike controlled and directed it. During this conflict several persons were killed, martial law was declared, and certain county officers were impeached for failure to perform their duties in suppressing violence. A large number of miners were arrested by the temporary authorities and imprisoned in a stockade known as the bull pen. Persons desirous of securing work in the mines at that time were forced to obtain a permit, which was issued only after the applicant had signed a statement denying that he had participated in the riot of April 29, declaring his belief that it was incited and perpetrated by the miners' unions, expressing disapproval of the riot, renouncing membership in the miners' union, and pledging himself thereafter to obey the law. The Western Federation of Miners conducted in 1913 the Michigan copper strike, although the organization had gained no foothold there before the strike, and officially advised the copper miners against inaugurating a strike before establishing a solid organization. In 1913 there were 180 local unions affiliated with the Western Federation, with nearly 45,000 members. The unions were distributed through 22 States, chiefly in the Rocky Mountain and Pacific region and in Canada and Alaska. From 1896 to 1898 the organization was affiliated with the American Federation of Labor; from 1898 to 1905 with the American Labor Union; and in 1905 it took part in organizing the I. W. W., with which it remained connected until 1906. In 1911 it again became affiliated with the American Federation of Labor. The official organ is the *Miners' Magazine*, published monthly at Denver, Colo.

MINERS' ANÆMIA. See ANKYLOSTOMIASIS.

MINERS MILLS. A borough in Luzerne Co., Pa., about 3 miles northeast of Wilkes-Barre, on the Delaware and Hudson, the Central of New Jersey, and the Lehigh Valley railroads (Map: Pennsylvania, K 4). The surrounding region yields a fine grade of anthracite coal, and besides the mining interests, the town contains a flour mill, a brick plant, and ironworks. Pop., 1900, 2224; 1910, 3159.

MINERSVILLE. A borough in Schuylkill Co., Pa., 4 miles west of Pottsville, with which it is connected by an electric road, on the west branch of the Schuylkill River and on the Lehigh Valley, the Philadelphia and Reading, Pennsylvania, and the People's railroads (Map: Pennsylvania, J 6). It is in the anthracite coal region and has extensive coal-mining interests and underwear factories. Pop., 1900, 4815; 1910, 7240.

MINERVA (Old Lat. *Menerva*, from root seen in Lat. *mens*, *memini*, *mones*, Skt. *man-*, Gk. *mēnos*, *menos*, spirit, strength. Minerva is thus the Thinker. The name Athena, Gk. *Ἀθηνᾶ*, has not been satisfactorily explained. Πάλλης, *Pallas*, at first an epithet of the goddess, but later used as a name, has been connected with *παλλακή*, *pallakē*, a maiden). A Roman goddess identified with the Greek Athena. Though the two divinities have some resemblance, it will be best to treat them separately.

Greek. Athena, called also Pallas Athena, or, simply, Pallas, was a universally worshiped Hellenic divinity, and there is no satisfactory evidence of a foreign origin for her cult. In the earliest literature we find Athena already a fully developed personality, the favorite daughter of Zeus, wielder at times of his ægis (q.v.), and but little inferior to him in power. In general the goddess was warlike. Hence she was worshiped in the citadel of many towns, and her sacred images, the Palladia, which were often said to have fallen from heaven, were kept with great care, for their possession made the town impregnable. (See PALLADIUM.) She is not, however, connected with the mere lust of battle, but with military wisdom and patient strategy as well as with heroic prowess in actual conflict. Wisdom is, in fact, so prominent in the conception that later she became the patron of learning. Even in early times she is Ergane, the Worker, the goddess of crafts, especially the feminine occupations of spinning and weaving. This conception of her may have arisen from the custom of weaving for the statue of the goddess a peplos or mantle. Athena was also the goddess of smiths, and even of agriculture, so that at Athens the smiths and potters celebrated the *Chalkœia* as a joint festival of Hephæstus and Athena. As a battle goddess, she was worshiped at Athens as Athene Nike, bearing the spear and shield, and wearing the ægis, which is commonly adorned with the Gorgon's head, of petrifying power. As Ergane she carries the spindle; as Nike she carries a pomegranate. Sacred to her were also the snake and the owl, and especially the olive, which she was said to have given to Athens, her favorite city. In the Greek belief she was the pure virgin, but there are plain traces that this was not original.

Athens is for us the great centre of Athena worship, and here there were two ancient shrines, the Palladium in the lower town, the seat of an ancient court for the trial of involuntary homicide, and the Acropolis, where were the house of Erechtheus and the shrine of Athena Polias, Protectress of the City. Here was an ancient temple, burned by the Persians, but possibly rebuilt, at least in part. Close to its site was built, near the end of the fifth century, the somewhat complicated Erechtheum (q.v.), and earlier (437 B.C.) the Acropolis was crowned by the magnificent Parthenon (q.v.), containing the gold-ivory statue of the goddess by Phidias. In her honor were celebrated the Panathenæa (q.v.) and other smaller festivals, at some of which mystic rites were prominent. According to the common legend she was born from the head of Zeus, who produced her by his own power. Other versions told how Zeus had swallowed METIS (Wisdom) when pregnant by him of Athena. In the fullness of time Hephæstus or Prometheus or Hermes, to relieve the pains in the head of Zeus, split it with an axe, whereupon the goddess leaped forth full-armed—a scene frequent in the earlier vases. The nature of Athena is still a matter of dispute. To Roscher (see below) there is much in favor of the view that she is a goddess of the lightning. Farnell rejects this view, and finds mental and moral rather than physical elements predominant in the cult of the goddess from the beginning; he regards her rather as the director of the intellectual life of mankind, in all its varied aspects, peaceful and warlike both.

Lexikon der griechischen und römischen Mythologie, vol. i (Leipzig, 1884-90); L. R. Farnell, *The Cults of the Greek States*, vol. i (Oxford, 1886); "Athena" in Pauly-Wissowa, *Real-Encyclopädie der classischen Altertumswissenschaft*, vol. i (Stuttgart, 1896); Jane E. Harrison, *Prolegomena to the Study of Greek Religion* (1903; 2d ed., Cambridge, 1908); O. Gruppe, *Griechische Mythologie und Religionsgeschichte* (2 vols., Munich, 1906); Arthur Fairbanks, *The Mythology of Greece and Rome* (New York, 1907); id., *Handbook of Greek Religion* (ib., 1910).

Roman. Minerva seems to be an old Italian goddess, patroness of handicrafts of all sorts, whose worship was also common in Etruria. She was not originally one of the leading Roman divinities, for her name is absent from the oldest religious calendars. When her worship was introduced is not known, but it was certainly early, for Minerva is one of the Capitoline triad, and was worshiped with Jupiter and Juno in the great temple of Jupiter Capitolinus, built by Tarquinius Priscus (see CAPITOL). She had also an ancient temple on the Aventine, which was the religious centre for the guilds of craftsmen, whose patron the goddess was. The festival of this temple was celebrated on March 19, the fifth day after the Ides (whence the name of the festival, Quinquatrus, or Quinquatria), and seems to have formed originally part of a festival of Mars. In time Minerva herself became patroness too of the arts of war. This festival was chiefly celebrated by the guilds, including physicians (whence was worshiped a Minerva Medica), dramatic poets, and actors, and was of a distinctly popular character. (For Minerva as patroness of learning, see ATHENÆUM.) On the Capitol Minerva appears in her Greek aspect as protector of the city, but this and her worship as a goddess of battle or victory seem due entirely to foreign influence. In the later Republic and the Empire the Greek conception of Athena almost completely supplanted the earlier Italian belief. Thus the Palladium (q.v.) kept at Rome in the temple of Vesta was believed to be an image of Minerva. Consult: W. W. Fowler, *Roman Festivals* (London, 1899); G. Wissowa, *Religion und Kultus der Römer* (2d ed., Munich, 1912); C. M. Gayley, *The Classic Myths in English Literature and in Art* (2d ed., Boston, 1911).

MINERVA MEDICA, TEMPLE OF. The name erroneously given in the seventeenth century to the ruins of a decagonal nymphæum on the Esquiline in Rome, formerly belonging to the Licinian Gardens, or, according to some authorities, to the Thermæ of Gallienus (c.250 A.D.). The name was wrongly based on that of the famous statue in the Vatican Museum miscalled Minerva Medica, which was not found on the Esquiline, but near the church of Santa Maria sopra Minerva. The 10 sides of the nymphæum, once adorned with mosaics and porphyry, are occupied on the lower story by a door and nine niches, with 10 windows above them. It was covered by a dome which was destroyed in 1828 and which was the earliest example of a dome above a drum of windows with buttresses between. When the ruins were excavated in the sixteenth century numbers of statues and architectural marbles were recovered.

MINERVA PRESS. The name of a London printing house, from which issued, late in the

eighteenth and early in the nineteenth century, an immense number of sentimental and trashy novels.

MINERVINO MURGE, *mă'nēr-vē'nò mōōr'jā*. A walled town in the Province of Bari delle Puglie, Italy, situated 25 miles southwest of Barletta (Map: Italy, F 4). It produces fruit, vegetables, and oil. There are also large quarries and limekilns. Pop., 1901, 17,353; 1911, 19,325.

MINES, BUREAU OF. A bureau of mining, metallurgy, and mineral technology in the Department of the Interior of the United States whose general function is to conduct, in the public interest, inquiries and scientific and technological investigations concerning mining, and the preparation, treatment, and utilization of mineral substances, with a view to improving health conditions and increasing safety, efficiency, economic development, and the conservation of natural resources, as well as to inquire into the economic conditions affecting these industries, and to disseminate general information having to do with mines and minerals. This bureau was established by Act of Congress, approved May 16, 1910, and became effective on July 1 the same year. The organic act establishing the bureau provided that the Secretary of the Interior should transfer to the Bureau of Mines from the United States Geological Survey the analyzing and testing of coals and other mineral fuel substances, and the investigations as to the cause of mine explosions. The various engineers, chemists, and other employees, also the equipment of the Geological Survey used for this work, were accordingly placed under the direction of the new bureau. It proceeded to carry on a number of important investigations having to do with such subjects as coal-mine explosions, explosives used in mining, especially those which, if properly used, will not ignite coal dust or coal dust and fire damp in small percentages; such explosives are tested and if they meet the rigid specifications are called "permissible" explosives for use in dusty and gaseous coal mines. Other investigations are: the use of electricity in mining, and the testing and approval of safety lamps, mine rescue, and first-aid apparatus. An important function of the bureau's work is the gathering of coal samples in mines and from shipments of coal for use by the navy, the army, the Panama Canal, and for the government buildings. The samples are analyzed, and larger shipments are tested in boiler plants and on vessels belonging to the government. Samples of coal gathered by geologists of the United States Geological Survey in their investigations are analyzed in the bureau's laboratory. The results of all coals sampled and analyzed are published from time to time in bulletins. The scope and purpose of the bureau were widened in a subsequent organic Act, approved Feb. 25, 1913, to include quarrying, metal mining, and metallurgical investigations and mineral fuels; and its work has since been conducted with vigor and valuable researches and publications have followed. The Bureau of Mines is under a director, Joseph A. Holmes, and includes, besides the administrative division, as organized in 1915, five technical divisions: mining, metallurgy, mineral technology, fuels (other than petroleum), and petroleum, including natural gas. The chief technical headquarters is at Pittsburgh, Pa., which is the largest coal-mining and steel-making centre. Extensive

testing is done here of mining appliances especially with reference to safety, and an experimental coal mine, chiefly for large explosion tests, is maintained by the bureau at Bruncton, 12 miles southwest of Pittsburgh. At this headquarters, chemical research as well as routine work is carried on. An analytical laboratory for testing fuels for government uses is maintained at Washington, D. C. A chemical laboratory is located at Denver for research work in connection with complex ores and rare metals like radium. Also in cooperation with a philanthropic institute, radium ores are concentrated and radium bromide produced for use in hospitals. At Salt Lake City, Utah, a cooperative laboratory is maintained for smelting and for electrometallurgical investigations. In San Francisco there are maintained laboratories for the investigation of smelter fumes and of methods of their prevention; also here, as well as in Pittsburgh, there are laboratories for petroleum and natural-gas investigations. These various investigations have already produced many valuable suggestions and results. Accounts, together with accident statistical information, have been published from time to time. Up to the end of the fiscal year 1914, 78 technical papers, 15 miner's circulars, and 82 bulletins had been published. Inspection of coal mines on government lands and in Oklahoma on "segregated" Indian lands, also in Alaska, is a function of the bureau. One of the most important parts of the bureau's work concerns the health and safety of workers in metallurgical and mineral concentration plants as well as in mines and quarries; however, as yet, in accordance with the terms of the appropriations, the chief safety and health investigations have been in coal mines. For the rescue of miners who may be entrapped by explosions or fires, mine-rescue corps under the leadership of district mining engineers have been maintained. While these men have assisted in many disasters, their chief function is to train miners in the use of oxygen-breathing apparatus and in first-aid methods. In its mine-rescue work and training work there are maintained mine safety cars equipped with apparatus for mine-rescue work and available to be sent to the scene of any mine accident but which normally travel in and around the principal mining districts, to give instruction to employees at each mine visited. In 1914 eight of such cars were in service, six in the principal coal fields, one in the Lake Superior iron and copper district, and one in the Rocky Mountain districts, while in Pittsburgh, Pa., and Birmingham, Ala., mine-rescue motor trucks able to transport nine rescue men with artificial breathing apparatus and first-aid supplies were available in case of disaster. The mine-rescue work of the bureau is done in cooperation with State officials and with mine operators. In addition to the cars and rescue trucks the bureau maintains six mine safety stations located respectively at Pittsburgh, Pa., Knoxville, Tenn., Birmingham, Ala., Urbana, Ill., McAlester, Okla., and Seattle, Wash., primarily for the purpose of training and instructing miners sent to these stations by operators or who come of their own initiative. Much suffering has been saved through the organization of first-aid crews. See **MINE ACCIDENTS**.

MINES AND MINING, IN LAW. The law relating to mines in the United States has been almost wholly developed within the last 65

years, or since the opening of the gold fields of California in 1849-50. By the common law of England all mines of gold or silver, wherever found, belong not to the owner of the land, but to the sovereign as an incident of the royal prerogative. There is some doubt as to whether this doctrine was ever generally adopted in the United States. It was, however, undoubtedly recognized by several Eastern States immediately after the Revolution, and in New York a statute, still in force, expressly reserves to the State the right to mines of gold and silver. In general, however, the government of the United States was considered to reserve all mineral rights in public lands conveyed or given to citizens, unless such rights were expressly granted. For a time the government leased mineral lands on royalties or fixed rents, but, owing to the great difficulty of ascertaining and collecting the amounts due, this policy was finally abandoned, and rights to take minerals were granted outright.

The law was in this condition when gold was discovered in California, and thousands of persons, many of them without previous experience in mining and with no knowledge of mining rights, rushed there and discovered and opened up mines. To avoid the frequent shedding of blood and other disagreeable consequences of disputes over the extent of each other's rights, it became the custom for the miners in a new district to meet and pass rules and regulations defining the rights of discoverers and miners, and these were enforced by committees appointed for the purpose. Subsequently, when courts were established in California, they adopted these rules and regulations, which had become so recognized and fixed in mining communities as to become in effect their common law. The claims of the miners were protected on the fiction that they had originally obtained a license from the government, and if they followed the rules of their particular districts they were held to have a property right in their mines, or claims, as they were called. These rights or claims could be conveyed, would descend to the heirs of the holder, and were in every way treated as real property. In July, 1866, Congress passed a law providing that title to public mineral lands might be acquired by payment of a small fee and by complying with certain prescribed formalities. This Act was superseded by the Act of 1873 (Rev. Stat., Tit. xxxii, c. 6), which substantially incorporated the provisions of the former Act and supplemented them with others suggested by the new development in mining practice, and which is the basis of the present mining law.

The Act of 1873 also provided for the judicial recognition of the rules and regulations then prevalent, and such as might thereafter obtain recognition in mining districts, where they were not contrary to its own provisions or the laws of the States in which such districts were situated. One of the important provisions of the last Act was to prescribe the maximum limits of claims. The extent of a lode claim, i. e., one where the ore runs in a well-defined vein, is fixed at 300 feet on either side of the vein by 1500 feet in length; and placer claims, i. e., where the ore is loosely mingled with the surface earth, are not to exceed 20 acres to one individual, or 160 acres to an association of individuals. The areas of both lode and placer claims may be changed by the statutes of the States in which they are

situated or by the rules of the mining district, provided they do not exceed the above-defined limits. The owner of a claim may follow a well-defined vein of mineral for 3000 feet from the opening of the shaft in any direction, and he may follow a vein the general course of which is downward through its "dips" and variations indefinitely.

The common-law rule that a man owns everything directly beneath the surface of his land is, therefore, not followed in the modern law relating to mines. It often happens that two lodes intersect, and in such a case the one who first opened his mine is entitled to the ore at the point of intersection; but each is entitled to follow his lode farther, and each has an easement or right to cross the tunnel of the other at that point in the proper working of his mine. Owing to the great difficulty in ascertaining whether a person in following his own vein is or is not trespassing on another's lode, any owner of lands who has reasonable cause to believe that another is doing so may obtain from a court of equity an "order of inspection" to determine whether the latter is encroaching on the land of the complainant or not.

Rights to water, which is so essential in mining operations, vary in different jurisdictions; but in general the one who first appropriates the waters of a stream for his use in mining is conceded the right to use all that is reasonably necessary in his operations. However, when some one else locates on the same stream the first person can continue to take only the amount he was using when the second person located his claim. The owner of a mine must properly support the earth surrounding his tunnels, and is liable for any damage caused to the lands of others by settling of the earth if due to his negligence in this respect. The rules and customs of the miners which were given the effect of law by the Statute of 1873, and those which have since come into existence, are too numerous and complicated to be set forth in the scope of this article. However, it may be said that in the present state of the law the courts, in deciding a case involving mining law, take into consideration, in the order mentioned, the statutes of the United States, the laws of the State in which the property in question is situated, and the rules and customs above referred to.

Any citizen of the United States, or a person who has declared his intention to become such, may locate and obtain a patent for a mining claim on public lands. Before a person can acquire any rights he must have actually discovered the presence of minerals. The first step thereafter is to make a "location" on the land claimed, i. e., to perform certain acts which are deemed to constitute sufficient evidence of an intention to claim the benefits of the discovery. The United States statutes provide that a claim must be "distinctly marked on the ground so that its boundaries can be readily traced." This is usually done by setting up boundary monuments, such as posts or stones, at the four corners of the claim. In most States the locator, as the prospector is called, is required to post a written notice of his claim on some object on the land. This notice consists of a description of the land thus appropriated and a declaration of his intention to occupy it for mining purposes. Such notice of claim must also be filed with a recording officer, usually the register of deeds of the county. After a miner has located his claim

in the above manner he must continue his mining operations or he will be deemed to have forfeited it. The labor may consist in actual mining, or in improvements in the mine for preservation or increased convenience in working it. When a claim is forfeited by a failure to perform labor of the required value it is open to relocation by any one. However, under this statute the claim is not forfeited until the expiration of a year from the time operations ceased. A claim may also be lost by abandonment, which consists in leaving a claim with an intention not to return and work it again.

Where a mining prospector complies with all the formalities required by law to obtain a location he has a good title against every one except the United States. In order to complete his title and make it a matter of record, the locator may obtain a patent, i. e., a grant, of the claim from the Federal government, by having a

MINES AND MINING, MILITARY. The term "military mining" is used in two senses. The first covers the placing and explosion of charges of explosive underground with a view to destroying men, matériel, and communications. It includes the ordinary use of mines as one of the obstacles to the approach of an attacking force. The other and more specific use of the term is to denote one of the stages in a sub-

MINING OPERATIONS AT GRAUDENS, 1902.

survey and an abstract of his possessory title made and filing them in the United States Land Office, together with a formal application for a patent and a certificate to the effect that he has expended at least \$500 on the claim, either in improving or working it. The application consists of an affidavit to the effect that he has complied with all local mining customs and regulations as well as the statutory requirements to obtain a good possessory title. One copy of this application must be posted on the claim and a notice thereof must be published in the nearest newspaper.

The rules of law in regard to the ownership, conveyance, and descent of real property are, in general, applicable to mining property. A tenant for life or years of mineral lands is entitled, as an incident of his tenancy, to work open mines thereon, but cannot, unless this right is expressly given, open new mines or revive abandoned mines without becoming liable for waste (q.v.). See LAND; REAL PROPERTY; WATER RIGHTS.

Bibliography. H. N. Copp, *United States*

born siege and in trench warfare. In the discussion of siege and siege works (q.v.) it is shown that when the attacking or besieging troops are no longer able to advance in the open, progress is made by approaches and parallels, in the hope that, if the besieged is not first starved, the besieger may advance close enough under the protection of his own trenches for the delivery of an overground assault. Occasionally, however, the relative force and skill of the combatants are such that the besieged may bring the approach of the besieger by surface trenches to a standstill. This is accomplished by his heavier gunfire or his greater skill supplemented probably by underground tunnels and countermines which so threaten an overland advance as to make it impracticable. When thus checked the attacker must resort to military mining if he wishes to advance further.

From the last advanced open position he has been able to construct the besieger proceeds underground by a system of shafts and galleries. These vary in size. In general the start is made with large galleries gradually ramifying into

smaller but more numerous galleries whose heads are close together. The principal types recognized in the textbooks are *great* galleries with a height of 6 feet and width of 7 feet, *common* galleries with the same height and half the width, *half* galleries with a height of 4½ feet and width of 3 feet, and *branches* with a height of 3½ feet and width of 2½ feet. The accompanying cut indicates the methods in which these branches develop. The shafts and galleries are usually lined with board casings 2 to 4 inches thick, or with heavy frames placed at intervals holding in position thin sheeting. For the work of excavating special tools are provided, shorter than those used aboveground. Provision is made at frequent intervals for ventilating the tunnels sufficiently to permit the miners to work. Passage from one level to another is by shafts or by inclined slopes. Great care is taken in the preparation of a map, corrected to date and showing the position of the various tunnels and branches, and their relations to each other, both in plan and in elevation. A similar system of tunnels is constructed by the besieged. As the two systems approach each other it becomes the object of each combatant to destroy the system of the other. In doing this the besieger is also normally desirous of forming a crater reaching to the ground above which he can occupy with his troops, thus obtaining new points of vantage on the surface. To prevent the formation of such positions the besieged endeavors to effect his explosions without breaking the surface of the ground.

The tendency in surface warfare is also towards a greater use of trenches both for positions and communications. When the trenches approach each other closely resort is naturally had to mining as one of the means of attack. Small branch galleries are run forward well below the surface and mines placed and exploded

SHAFT LINING.

under important points of the enemy's line, as magazines, batteries, and intersection of crossing trenches.

The explosives used in mines and mining have been gunpowder, gun-cotton, dynamite, and mixtures of dynamite with other high explosives. The quantity of explosive to be used depends upon the result desired. A *common* mine is one in which the crater formed has a diameter at the surface approximately twice the depth. Mines with larger charges of powder than will produce this result

are known as *overcharged* mines; with less, as *undercharged* mines. When given a charge so small that no crater is produced on the surface they are called *camouflets*. To produce a common mine the charge varies considerably with

the nature of the soil. The general rule for them with gunpowder in ordinary earth is that the charge must be equal in pounds to one-tenth the cube of its distance in feet below the surface.

Mining operations were conducted upon a large scale at the siege of Sebastopol in 1854 and 1855, where the Russians, under the lead of the accomplished engineer, General Todleben, were able to withstand the allies a period of 349 days. Mining was carried on in the sieges of Vicksburg and Petersburg in the Civil War, and in that of Port Arthur in the Russo-Japanese War. Military mining has played an important part in past wars at critical times, and it is probable that in a form adapted to the changing conditions it will always be a big factor in large and protracted land wars. The subject of siege works and military mining is treated in Mercur, *Attack of Fortified Places* (New York, 1894), in the *Chatham Manuals*, especially part iv (London, 1883), and in *Engineer Field Manual*, United States War Department. For submarine mines and torpedo defenses, see MINE, SUBMARINE; TORPEDO; TRENCH, MILITARY.

MINETTE, mé'nēt' (Fr., dim. of *mine*, mine, whence Rhenish Ger. *Minette*, iron ore). An igneous rock of granular or porphyritic texture, composed essentially of orthoclase feldspar and biotite. In contrast with the granites, syenites, and diorites, to which it is related, it is rich in ferromagnesian minerals, and hence has a darker color. Minettes generally occur in dikes, and are quite susceptible to weathering agencies.

MINE WORKERS OF AMERICA, THE UNITED. The largest American labor union, whose declared object is "to unite mine employees that produce or handle coal or coke in or around the mines, and ameliorate their condition by means of conciliation, arbitration, or strikes." The officers consist of a president, vice president, and secretary treasurer, who, together with one delegate from each of the 29 districts into which the jurisdiction of the United Mine Workers is divided, constitute the National Executive Board, which has the power to levy assessments and to order general strikes by a two-thirds vote. The government of the union is thus highly centralized. In organization the United Mine Workers is an industrial union, aiming to unite not only miners, but all skilled and unskilled laborers working about coal mines, except mine managers and top bosses. This policy of industrial organization has brought the union into conflicts with the unions of the stationary firemen and of the blacksmiths. In operation the United Mine Workers is a typical new union of the aggressive type. It maintains no extensive system of fraternal benefits, but devotes the greater part of its revenue to the support of strikes and the organization of new unions. Thus, out of the total expenditures of \$2,102,261 in 1913, \$1,621,942 were appropriated to aid and \$290,764 to salaries and expenses of officers and organizers. The control of local strikes rests partly with the national officers. Any local union may strike provided it obtains the consent of the district officers and the national president, but in case either disapprove, an appeal for the permission "to strike may be made to the executive board. Any local union striking in violation of the above provisions shall not be sustained or recog-

nized by the national officers." This seems to constitute the only penalty for unauthorized strikes. In the bituminous districts of Illinois, Indiana, Ohio, and Pennsylvania strikes have been practically eliminated by the annual joint conference, or collective bargaining, between the miners and operatives, in which a scale of prices for the following year is adopted and the settlement of further differences provided for by local boards of arbitration. The United Mine Workers was organized Jan. 25, 1890, but its membership decreased rather than increased until the great bituminous coal strike of 1897, during which year the average membership was only 9731. Since that time the membership has increased by leaps and bounds, and in 1905 the national union had an average paid-up membership of 264,950, which increased to 377,682 in 1913. For December, 1913, the paid-up membership was 415,142, distributed among 29 districts and about 3000 local unions. The greatest gains were coincident with the anthracite strikes of 1900 and 1902, the latter of which, lasting more than five months and involving 147,000 workmen, is perhaps the most important strike in American history. The official journal is *The United Mine Worker*, published weekly at Indianapolis. Reports of the biennial conventions, published at Indianapolis, offer much valuable information relating to the organization. See TRADE-UNIONS.

MINGHETTI, min-gét'té, MARCO (1818-86). An Italian writer and statesman. He was born at Bologna, Nov. 8, 1818, of a wealthy family, and after a university course in political science made a study of the institutions of France, Germany, and Great Britain. On his return to Italy he published an essay on the great commercial advantages of free trade, as existing in England, and espoused with warmth the economic views of Richard Cobden, for the assimilation of which he had been prepared by a knowledge of the teachings of the Tuscan economist Bandini. In 1846 Minghetti began his political career by starting at Bologna a journal of liberal tendencies, *Il Felsineo*; by 1847 he had made such a name for himself that he was called to Rome by Pius IX to become a member of the *Consulta delle Finanze*, and in 1848 he became Minister of Public Works. After the papal change of front, however, Minghetti withdrew from office and joined the army of Charles Albert in Lombardy, where he was warmly received by the King and appointed to the royal staff with the rank of captain. After the battle of Goito he was made a major and distinguished himself in the engagement of Custoza (July 25, 1848). In the autumn of the same year Minghetti was invited to Rome by his friend Count Rossi as a member of the new constitutional ministry. He arrived the day of Rossi's assassination, and after refusing the Pope's request that he take the place of the murdered Minister he returned to the Piedmontese army. On the disastrous conclusion of the war Minghetti resumed his study of political economy and gained the confidence of Cavour, by whom he was consulted during the conferences of Paris. In 1859 he became Secretary General in the Ministry of Foreign Affairs, but resigned with Cavour upon the conclusion of the armistice of Villafranca. Minghetti became Minister of the Interior under Cavour in 1860 and after the death of Cavour held the portfolios of the Interior under Ricasoli and of Finance

under Farini. In March, 1863, he became Prime Minister. He left office in 1864. He went as Ambassador to London in 1868 and was subsequently for a short time at the head of the agricultural and commercial department in the Menabrea ministry (1869). He was Ambassador to Vienna in 1870-73. From 1873 to 1876 he was again at the head of the cabinet, first as Minister of Finance and later as Minister of Foreign Affairs. He spent the last years of his life in study and partial retirement and died at Rome, Dec. 10, 1886. Among his chief writings are: *Del' economia pubblica*, etc. (1859); *Opuscoli letterari ed economici* (1872); *Stato e chiesa* (1878). His speeches in Parliament (*Discorsi parlamentari*) were published in Rome in 1888-90. He was also a student of the fine arts, and, besides lecturing on Raphael and Dante, he produced a work, *Le donne italiane nelle belle arti al secolo XV e XVI* (1877), and a biography of Raphael (1885). His autobiography, *I miei ricordi* (Turin, 1888), appeared after his death.

MINGO (mín'gò) **JUNCTION**. A city in Jefferson Co., Ohio, about 12 miles northeast of Urbana, on the Pennsylvania Company, the Pittsburgh, Cincinnati, Chicago, and St. Louis, and the Wheeling and Lake Erie railroads (Map: Ohio, J 5). The Carnegie steel works comprise the only manufacturing plant. Farming, dairying, and fruit growing are carried on, and some coal is found in the vicinity. The city owns the water works. Pop., 1900, 2954; 1910, 4049.

MINGRELIA. A former independent feudal state of the Caucasus, bordering on the Black Sea, now included in the Russian Government of Kutais (Map: Russia, F 6). It was a vassal state of Georgia until 1414, when it became independent under its own princes, although tributary to Turkey and Persia. Russia obtained control over it in 1803, but the internal administration was left in the hands of the native chiefs until 1867, when, as a result of a series of peasant uprisings begun in 1857, it was finally annexed by Russia. The inhabitants are mostly Mingrelians, closely allied to the Georgians. Mingrelia is the ancient Colchis.

MINGRELIANS. A tribe of the Kutais region, numbering some 250,000 and belonging to the Georgian group of peoples of the Caucasus. (See MINGRELIA.) In stature they are above the average, and, like the Georgians proper, many of them are of great physical beauty. The Mingrelian language varies considerably from the Georgian prototype. Of the character of the Mingrelians many investigators have entertained no high opinions, setting them down as lazy and unprogressive. The Mingrelians, as are the other Georgians, are more or less Christian. They have a folk literature, consisting of legends, songs, etc., the people being fond of music, the dance, etc. Consult: Telfer, *The Crimea and Transcaucasia* (London, 1876); Chantre, *Recherches anthropologiques dans le Caucase* (Paris, 1885-87); Erckert, *Der Kaukasus und seine Völker* (Leipzig, 1887); Bryce, *Transcaucasia and Ararat* (London, 1897); and, for their place among the Caucasian people, A. Dirr, "Anthropologische und ethnographische Uebersicht über die Völker des Kaukasus," in *Petermann's Mitteilungen*, vol. lviii (Gotha, 1912). See GEORGIANS.

MINHO, mé'nyó. A river of the Iberian Peninsula. See MINO.

MINHO. A province of Portugal. See *ENTRE DOURO E MINHO*.

MINIATURE PAINTING. Painting in small dimension and of delicate workmanship, usually in water color on vellum or ivory. The term is derived from *minium*, Latin for red lead, a pigment used in illuminating manuscripts, and it was first applied to the pictures which illustrated manuscripts. (See *ILLUMINATED MANUSCRIPTS*.) Portrait miniatures appeared in devotional manuscripts as early as the late thirteenth century, one of the earliest being a likeness of St. Louis in the *Credo* of Sire de Joinville (c.1287). They attained their highest excellence in the Netherlands and northern France during the fifteenth and early sixteenth centuries. With the introduction of printing, miniatures in manuscripts disappeared; but the transition to the miniature in the modern sense had already been accomplished. This latter is usually a single portrait, oval in shape and from 2 to 4 inches high. Early German and Netherlandish painters sometimes painted them in oil on copper, but they were most frequently executed in water color on vellum, sometimes on chicken skin or cardboard. The use of ivory for this purpose began in the late seventeenth century, but did not become general until the eighteenth. Its introduction changed the character of miniature painting, as more transparent and delicate colors could thus be achieved. This adapted the art especially to the portrayal of flesh tints and other feminine charms, with the result that women replaced men as the principal subjects of miniatures. Miniatures in enamel became popular from about the middle of the seventeenth century, and the subsequent practice of presenting snuff-boxes, cardcases, and other favors greatly promoted the form of the art, particularly in France. During the eighteenth century the increasing demand for tiny miniatures for use in locketts, bracelets, and the like, led to the practice of stippling, in which the color was applied in minute dots, with fine technical effects, but to the detriment of character and sacrifice of general effect.

History. The great charm of miniature painting consists in the intimate view it affords of the sitters, often persons of historical importance. Princes and rulers have always patronized the art, and it has consequently flourished in the national capitals of England, France, and other north European countries. One of the earliest and greatest representatives of the art was Hans Holbein the Younger (1497-1543), whose miniatures have the same qualities as his larger portraits and contain a remarkable grasp of character, with breadth of treatment, impeccable detail, and clear, strong color. His influence is especially evident in the clear and precise art of his follower, Nicholas Hilliard (1537-1619), and in the more richly colored miniatures of the latter's son Lawrence. Isaac Oliver's (c.1567-1617) art is more strongly characterized and both he and his son Peter gave greater roundness to the figures. The greatest master of the seventeenth century was Samuel Cooper (1600-72), who united Van Dyck's elegance with breadth and dignity, in his remarkable portraits of the men of the Commonwealth. The art declined during the early eighteenth century, but again reached a climax in the work of Richard Cosway (1741-1821), the most popular of English miniaturists, whose

gently idealized portraits of women are painted with consummate mastery of delicate color. Of his followers, George Engleheart's art was more virile than his master's; Andrew Plimer was rather insipid, while John Smart united power and refinement. During the nineteenth century, concomitant with a general decline of the art, the so-called large miniature came into vogue, measuring as much as 50 centimeters in height, and characterized by breadth of treatment rather than finish, as may be seen in the works of Andrew Robertson and Sir William Ross. The invention of photography had a disastrous effect on miniature painting, diminishing both the demand for it and the necessity of painting directly from the sitter. The end of the nineteenth century witnessed a general revival.

In France the art was as prolific and important, especially during the eighteenth century, as in England. It was introduced from Flanders by Jean Clouet (died 1540), whose work was continued by his son François and others; but few of these early miniatures can be identified with certainty. The greatest French miniaturist of the seventeenth century was Jean Petitot (1617-91), the first successfully to use enamel. He adopted the style of Van Dyck and invented several new colors, particularly for rendering the flesh tints. His gifted son, Jean Petitot, and numerous followers continued his traditions, which long dominated enamel painting. The most prominent of the stipple engravers was Jean Baptiste Massé (1687-1767). Pierre Adolphe Hall (1739-93), a Swede by birth, excelled all contemporary artists in an art as delicate as it was free and powerful. Many distinguished painters of the eighteenth century practiced also in miniature; such as Largillière, Nattier, and especially Fragonard, who, unhampered by tradition, painted miniatures in a style similar to his canvases. The most popular miniaturists of the Napoleonic era were Dumont, Isabey, and especially J. B. Augustin.

In Germany the art was practiced during the sixteenth century by many early painters, like Lucas Cranach the elder, Ludwig tom Ring, and others. Rosalba Carriera (1675-1757), the talented Venetian, painted miniatures not unlike her pastels, and possessing a certain spiritual quality. Both she and her pupil, Felicitas Sartori Hoffmann, who settled at Dresden, exercised a wide influence upon the German school. This school culminated in the work of Heinrich Friedrich Füger (1751-1818), who practiced chiefly at Vienna, which early in the nineteenth century was an important centre of miniature painting. In the Netherlands, Scandinavia, and Russia the art was also practiced with varying success.

In the United States most of the early painters also attempted miniatures, notably Copley, Gilbert Stuart, C. W. Peale and others of his family, and John Trumbull. But the most important miniaturist of the early period was Edward Greene Malbone (1777-1807), who combined good drawing with an innate feeling for beauty and grace. The general decline of the art during the nineteenth century was followed by an important revival in the late nineties. The American Society of Miniature Painters, founded in 1899, holds annual exhibitions in New York. Its president, William J. Baer, and Laura C. Hills, pioneers in the art, occupy

places of the first rank. Other important artists are Lucia Fairchild Fuller, Martha S. Baker, Florence Mackubin, Virginia Reynolds, L. A. Josephi, W. J. Whitmore and J. W. von Rehling-Quistgaard. American miniature painting is characterized by animation, truth to nature, and the use of clear, bright color.

The most important collections of miniatures are in private possession. One of the finest is that of the late J. P. Morgan (Metropolitan Museum of Art, New York), with examples of nearly all of the prominent English and French miniaturists. Other notable collections belong to the King of England, the German Emperor, the Czar of Russia, King of Sweden, Queen of Holland, and other sovereigns. Among the museums owning good collections are the University Galleries, Oxford; the Wallace collection, London; the Louvre; the Rijks Museum, Amsterdam; and the museums of Dresden and Vienna. There are a number of important private collections in England.

Bibliography. J. L. Propert, *History of Miniature Art* (2 vols., London, 1887), is still valuable from the collector's point of view. Another important work is J. J. Foster, *Miniature Painters, British and Foreign* (2 vols., New York, 1903), and more recent still, Dudley Heath, *Miniatures* (London, 1908), containing a bibliography, and Lemberger, *Portrait Miniatures of Five Centuries* (ib., n. d.). The chief English authority on miniatures is G. C. Williamson, among whose works we cite the brief *Portrait Miniatures from the Time of Holbein* (London, 1897); *Andrew and Nathaniel Plimer, Miniature Painters, their Lives and their Works* (ib., 1903); *History of Painting in Miniature* (2 vols., ib., 1904); *Catalogue of the Collection of Miniatures of J. P. Morgan* (4 vols., ib., 1906), a monumental work. J. W. Bradley, *Dictionary of Miniaturists, Illuminators, Calligraphists, and Copyists* (3 vols., ib., 1887-89), is still valuable as a book of reference; also Ernest Lemberger, *Meisterminiaturen aus fünf Jahrhunderten* (Stuttgart, 1911); F. R. Martin, *Miniature Painting and Painters of Persia, India, and Turkey from the Eighth to the Eighteenth Century* (2 vols., London, 1912); Camille Faust, *Les miniatures de l'Empire et de la Restauration* (Paris, 1913); Fernand de Mély, *Les primitifs et leurs signatures*, vol. 1 (ib., 1913). See also the bibliography of ILLUMINATED MANUSCRIPTS.

MINIE, mē'dyā', CLAUDE ETIENNE (1814-79). A French soldier, ordnance expert, and inventor. He was born in Paris, entered the army as a volunteer, and served in Algeria during several campaigns. He became captain in 1849 and superintendent of the school of ordnance at Vincennes in 1852. In 1858 he was employed by the Egyptian government to superintend a manufactory of arms and a school of gunnery at Cairo. He invented the Minié rifle, which was brought out in 1849 and adopted by the French government, and is especially noteworthy in that it was the first practical introduction of the principle of expansion in the manufacture of projectiles and gave a precision and range previously unknown. The Minié bullet was a conical projectile of lead, hollowed out at the base. When fired the base of the ball expanded, to take the rifling. See SMALL ARMS.

MIN'IM, IN MUSIC. See MENSURABLE MUSIC.

MINIMA. See MAXIMA AND MINIMA.

MINIMITES (Lat. *fratres minimi*, least

brethren, so called, in token of still greater humility, by contrast with the *fratres minores*, lesser brethren, the original name of the Franciscans). A Roman Catholic religious order, founded by St. Francis of Paola (q.v.). Devout hermits began to gather round him as early as 1435, and in 1444 a convent was founded at Paterno. The order received papal confirmation in 1474. It spread first into France, when the founder was summoned thither by Louis XI. In Paris they were commonly known as *Bons Hommes*, from the popular name of an older community to whose house at Vincennes they succeeded; and in Spain, to which they next spread, they got the name of Fathers of Victory, from the fact that the recovery of Malaga from the Moors was ascribed to their prayers. The Emperor Maximilian invited them to Germany in 1497. Their first definite rule was not drawn up by the founder until 1493; it was exceedingly austere, forbidding the use not only of meat, but of all animal products, such as butter, eggs, cheese, and milk. The order at one time numbered 450 houses, but later fell into decay and is now represented by 17 convents in Italy, Sicily, and Sardinia, and one in Spain. The superior of a convent has the title of corrector, the head of the whole order being the corrector general. Francis also founded an order for women which never had more than 14 convents and is now almost extinct, and a third order (see TERTIARY) for persons living in the world. Consult D'Attichy, *Histoire générale de l'ordre sacré de Minimes* (2 vols., Paris, 1624), and Heinbuecher, *Die Orden und Kongregationen der katholischen Kirche* (Paderborn, 1907).

MINIMUM DEVIATION, ANGLE OF. See LIGHT.

MINIMUM WAGE. A term employed to designate the lowest level of earnings affording for a given class of laborers and those naturally dependent upon them means of existence adequate to maintenance in full physical efficiency and social decency. This minimum is difficult to define precisely, and varies from place to place, according to cost of food, housing, fuel, etc. In attempting to define the minimum, recourse is usually had to investigations of the physiologists as to the quantity and variety of food necessary to maintain a worker or a workingman's family in normal health. The results of such investigations, translated into money terms by means of tables of retail prices, supplemented by local studies of house rents, clothing costs, etc., afford the basal figures in minimum wage computations. The minimum thus defined for a normal working-class family in American cities varied from somewhat under \$1500 to \$1800 or a trifle more, according to prices prevailing in 1921.

The minimum wage movement is a concerted effort of workers and social reformers to force wages in the less well-paid trades to a level corresponding with the social minimum as above described. Organized labor in its more successful forms has established a level of wages well above such a minimum. Unskilled laborers often fall far below it, and especially is this true of immigrant labor and the labor of women and children. The discrepancy between wages and a decent minimum of subsistence is most shocking in the case of the sweated trades, where whole populations are sometimes kept in a condition worse than slavery, slowly succumb-

ing to malnutrition and its accompanying maladies.

The first state to undertake seriously to apply political means to the eradication of underpayment was the Australian colony of Victoria. By a law of 1896 boards were constituted in six trades with authority to fix minimum wages. The operation of the law was so satisfactory that it was later extended gradually in scope until in 1915 it covered 141 trades, employing over 150,000 workmen. The success of the Victoria experiment aroused great interest, after 1905, in the United States and Great Britain. Before the close of 1921 twelve American Commonwealths had enacted minimum wage laws. Of these Massachusetts and Nebraska provide for commissions with power to investigate and report on what would be an appropriate minimum wage in specified industries, but have made no provision for forcing employers to pay such wages. California, Colorado, Minnesota, Oregon, Washington and Wisconsin provide for commissions with power, after investigation, to fix rates legally binding upon employers. The State of Utah fixes a legal minimum by statute and makes it a penal offense for employers to pay less than the minimum. All American minimum wage laws, for constitutional reasons, are limited in their application to women and minors. Great Britain, by Act of 1909, established trade boards with power to fix minimum wages in the trades of chain making, machine-made lace finishing, box making and tailoring—notoriously sweated trades. After the great coal strike of 1911 an Act was passed setting up district wage boards in the coal-mining industry.

While the ideal of the minimum wage movement is the establishment of a living minimum in every trade, the practice of trade boards and commissions is much more conservative. Such boards and commissions content themselves with fixing such wages as are practicable, i.e., wages that can be paid without destroying an industry or driving it to another jurisdiction. Thus the minimum is rarely above the level already established by the better-paying establishments. In unorganized trades wages for similar labor vary widely, the establishments ill equipped with machinery or inefficiently managed making up their competitive disadvantage through low wages. The establishment of a minimum wage tends to drive such concerns out of business and thus concentrates production under the control of employers able to pay better wages. In this respect the operation of the minimum wage is similar in its effects to that of the union scale of wages. Like the latter, the minimum wage may become a means of gradually but progressively raising the general level of wages. In the United States the employing classes are, as a rule, though by no means universally, opposed to the introduction of the minimum wage principle. Organized labor also furnishes opponents to the principle, animated by the fear that its application will tend to the disintegration of the organizations. In Victoria, where the plan has passed beyond the experimental stage, opposition on the part of either labor or capital is practically nonexistent.

MINING. The art of working deposits of valuable mineral. The recovery and use of certain of the native metals was practiced by prehistoric peoples. Gold and meteoric iron were appreciated and searched for from very remote

times. Native copper from Lake Superior was extensively mined and used by the aborigines of America. With the advance of civilization, the knowledge of metals increased and ores, or metals in combination, were recognized and utilized and mining proper began. Reference to mining is made in the Bible, and other ancient records prove that the Phœnicians navigated the seas as far as Cornwall, England, in order to obtain tin ores for the manufacture of bronze. The Romans had extensive mines for iron ore in the island of Elba. They also worked the great copper deposits of Rio Tinto, Spain. The mines of Laurium, Greece, were famous in ancient times for their yield of silver. From the old mining districts of Cornwall and from the Erzgebirge and the Harz mountains in Germany miners have gone all over the world, and their skill and experience have done much towards developing mining practice as it exists to-day.

The present article will be confined to a discussion of the art of mining as applied to the working of underground ore bodies. For placer mining see the article GOLD; for coal mining see COAL; see also QUARRY; DRILL; WELL SINKING. The handling of the ores immediately preparatory to and during the processes involved in extracting the metals is of a nature different from that of mining proper and is frequently done at places far from the mines. These operations are considered in the articles on ORE DRESSING, METALLURGY, and in the sections devoted to the metallurgy of the various metals and in the adjunct articles there mentioned.

Prospecting. The search for and location of deposits of mineral is called *Prospecting*, and the men performing this work are known as *Prospectors*. The procedure in prospecting a tract of land suspected to contain mineral wealth is thoroughly to traverse it, and to note carefully the familiar indications of the presence of minerals. These indications are often numerous in kind for each mineral and they also vary for different minerals. Generally speaking, coal, gypsum, salt and similar nonmetallic minerals occur in unaltered deposits, i.e., in rocks which have not undergone metamorphism, while the metallic minerals are found in rocks that have undergone metamorphism. These are among the broad indications of the presence or absence of certain minerals.

The geologic age of the rocks is in respect to certain minerals an indication whether these minerals are likely to be found or not. For example, the major portion of the coal deposits of the world have been found in rocks of the Carboniferous age; they exist at times in rocks of subsequent ages but almost never in rocks of preceding ages. The presence of iron is indicated by rustlike staining of earth and rock. The presence or absence of vegetation may also indicate the existence of minerals, e.g., a bed of phosphate rock is commonly indicated by a line of luxuriant vegetation, and the outcrop of a metallic mineral deposit by a lack of vegetation. Beds or deposits of magnetic iron ore and of certain of the nickel ores are frequently located by their attractive influence on the magnetic needle. In prospecting for placers, search is made for existing or ancient watercourses in which deposits of placer material are likely to have been formed. In prospecting for petroleum, natural gas and bitumen, the surface indications looked for are springs of petroleum, oil, or

naphtha; porous rocks saturated with bitumen; springs, pools, or creeks showing bubbles of escaping gas or an iridescent coating of oil. The presence of a mineral deposit of probable economic value having been established, it then becomes necessary to secure title thereto.

Legal Considerations. The laws of the various countries governing this point naturally differ somewhat, and should be carefully studied and complied with. If the deposit is located on government land, a "claim" of variable size, according to the laws of the country or district, is staked out, and when this is opened up sufficiently to have necessitated the expenditure of a certain specified sum of money, a permanent title can be obtained. In the Western States of the United States, claims usually extend 1500 feet along the vein and 300, or less, feet on each side of it. The owner can then follow the vein in depth where it leads him between the vertical planes of his end lines, this irrespective of the vertical projection of his side lines. Because of the irregularity of veins, much litigation has ensued and the law of the United States is open to much criticism. Many authorities consider that it would be better practice to adopt square claims, conveying the mining right to all ore lying vertically beneath them. This is the practice in British Columbia and in Mexico, and is practically so in the eastern United States, where title to the land, unless special reservations are made, carries title to the mining rights. In some States, notably in New York, and in many foreign countries, the State claims peculiar and special proprietary rights to deposits of useful minerals. Much variety also prevails in America in the size of claims other than for deep mines. Gold-bearing placers, i.e., have special sizes depending on local regulations. See MINES AND MINING, IN LAW.

Exploration and Development. Having found a mineral deposit and having obtained a legal hold on its ownership, the next step is its exploration and development. Exploration implies the determination of the extent, the richness, and the physical conditions obtaining. Development implies the confirmation of the results of exploration, and the preparation for subsequent mining operations. As work along both these lines is ordinarily carried on simultaneously, they will be treated under the one heading. The methods which may be employed for the exploration and development of a mineral deposit are: surface excavation; underground workings; churn drilling; and core drilling. It is usually the case that a combination of two or more of these methods will be used.

Surface excavation is strictly a preliminary form of exploration, its object being to determine the surface extent and character of the deposit in order that other methods of exploration may be more intelligently directed. This type of work is extensively used at Cobalt, Canada.

Underground workings, either as shafts or tunnels, may or may not be used as a primary means of exploration. They are, of course, invariably employed in the development stage.

Churn drilling, or the projection of vertical holes of from 6 inches to 9 inches in diameter to considerable depth by means of a special mechanical arrangement (see WELL SINKING), is extensively used in exploring ore bodies of wide area and irregular form. The material recovered from drilling, consisting of mud and

gravel, indicates in a very satisfactory way the character and mineral contents of the rock passed through. Practically all of the so-called "Porphyry" copper properties recently opened have been explored in this manner.

Core drilling, or the projection of small holes 1 inch to 4 inches in diameter at any angle, with the recovery of cores of the rock passed through, gives excellent exploratory data. Unfortunately, however, this method is limited to those districts where the rock to be passed through is generally homogeneous in texture. It has been widely used in the Lake Superior copper, in the Michigan iron, and in the Sudbury nickel districts.

Mining. Having determined the extent, value and physical conditions obtaining, and granting that they indicate the mineral deposit to be of commercial importance, mining proper or the working of the deposit may be undertaken. The problems now presented are: magnitude of operations justified; method of working best suited to the conditions; the mechanical requirements.

Magnitude of Operations Justified. The question of the tonnage advisable to mine annually requires a balancing of four conditions, the total tonnage actually shown by the exploration and development work, the possibilities of finding future additional tonnages, the probable working costs, and the capital investment required. The two last mentioned items will naturally vary with the magnitude of the operations, therefore two or three cases within the legitimate possibilities of the property should be worked out. The desideratum is, of course, that scale of operation which will show the greatest ultimate net profit on the whole investment. In some special cases market conditions affecting the sale of the mine product must also be considered.

Method of Working to be Adopted. The successful solution of this problem requires careful consideration of the three main cost-making operations which enter into mining: the actual breaking down of the ore or stoping; the support of the excavated volume; and the transport of the broken ore to the surface. The governing factors in this consideration are: (a) the shape of the deposit; (b) its location with respect to the surface; (c) the physical character of the ore; (d) the physical character of the surrounding rock; (e) the cost of mine supplies (timber, power, etc.).

Stoping Methods.—The actual breaking down of the ore may be done by: overhand stoping; underhand stoping; side-cut stopes; or caving. Briefly described, the first two methods indicate the position of the workmen with respect to the body of ore to be broken. The third method, "side cut," the breaking of ore over horizontal areas, this usually preparatory to the fourth method or "caving," which implies the breaking down of the ore by its own weight or by the weight of overlying rock. The function of the workmen mentioned above is to drill holes in the rock or ore mass either by hand or by mechanical means. The holes so drilled are later loaded with an explosive which when fired shatters and breaks down the ore or rock.

Support of Mine Workings.—Because of the possible value or nonownership of the surface overlying an ore body it may become necessary to provide for the permanent support of the mined-out areas. Also in order to insure the safety of the workmen underground and to

facilitate mining operations it is invariably necessary to provide temporary support. The methods which may be employed to this end are grouped as follows: mineral pillars; stull timbering; square-set timbering; waste filling; ore filling.

Mineral pillars were probably the oldest form of mine support and are still used in many mines where the value of the ore left standing as pillars is less than the cost of other methods of support. Working by this method implies the removal of the ore from a number of rooms, leaving ribs of unbroken ore at intervals. The proportion of the ore so left to the ore mined depends upon the thickness of the mineral body, the physical character of the ore, and the strength of the roof-forming rock.

Stull timbering is used in connection with relatively narrow and highly inclined deposits of high-value ore. The procedure is to mine out the entire ore area, placing at intervals timbers at right angles to the walls. The amount and size of timber to be used depend on the inclination of the ore body and the strength of the wall rock. This method is universal, and examples are afforded in almost any precious-metal mine.

Square-set Timbering.—In ore bodies where the width mined is greater than can be conveniently spanned by a single stick of timber and where the values contained in the ore are high, square-set timbering may be used, the supporting timbers being built up either rough or squared and so mortised at the ends that they fit together like the edges of a cube, 6 feet on a side. Others fit in with them, each stick entering into four adjacent cubes, and in the end a framework of timber of great strength is built up. This method of mine support was formerly extensively used at Butte, Mont., and at Bisbee, Ariz. Latterly, because of the excessive cost of timber, this method is being discarded.

Waste Filling.—This method, because of high costs for timber, is now widely used both in narrow and wide veins where the value of the ore warrants its complete removal. The procedure is to fill the worked-out volume with either waste rock or with the crushed rock discarded from ore-dressing operations, the only timber used being for temporary support at the immediate working faces and for the maintenance of passageways at intervals through the fill for the removal of ore.

Ore filling, or shrinkage stoping, is used when it is desired to afford a temporary method of support both in those types of ore bodies described as suitable to stull and square-set timbering and in those ore bodies of irregular form which it is intended ultimately to work by caving methods. The system is to break down the ore by overhand stoping and to allow the major portion of it to remain in the stope until mining is completed, only sufficient being drawn off to leave space at the face for the workmen.

Caving.—As the name implies, in this system of mining provision is made only for the temporary support of the overlying rock or ore. When preliminary mining operations have proceeded sufficiently far the temporary supports are withdrawn or broken down, the overlying unsupported mass caving by its own weight or by the weight of the overlying rock. In this manner a large proportion of the ore may be broken without the use of labor or powder.

Also a very material saving is made in not having to support the excavated volume. The conditions which make a caving system possible are an ore body of large area and a surface of no value. The mining and support of the first portions of an ore body which is to be worked by caving will make use of some one method or a combination of methods already described under the heading of mineral pillars, square-set timbering, or shrinkage stoping. Caving is widely used at present in the mining of the so-called "porphyry" copper deposits, in the iron mines of Michigan and Minnesota, and in the Kimberley, South Africa, diamond mines.

Mechanical Requirements. The application and selection of mechanical means to assist in mining operations require careful consideration involving the means which may be employed, the capital investment required, the life of the mine, and the saving in cost per ton to be effected. Many a mine has been equipped with an expensive mechanical outfit which while possibly well thought out from the mechanical engineer's viewpoint has not been justified by the life of the mine. On the other hand, it is frequently the case that a mine may be under-equipped, that the investment of capital in proper machinery would effect a saving in the per-ton cost which would mean the difference between a loss and a profit. In no industry does the saying that "the means must fit the end" hold more true than in mining.

The economics of the case having indicated that the use of machinery is justified, the first question is the choice of the primary motive power. This choice lies between the use of steam, as generated by the burning of wood, coal, or oil; gas, as generated and used direct from wood, coal, or crude oil; electricity, as purchased from power companies or as generated from local hydraulic power.

Having decided upon the cheapest, all things considered, prime mover, the next problem is the consideration of the uses to which the machinery may be applied. These may be divided according to location into (a) underground mechanical equipment and (b) surface mechanical equipment.

Underground mechanical equipment may be further classified into machines facilitating such operations as drilling, transport of broken ore or rock, and pumping.

Mechanical Drilling Machines.—These machines have as their object the drilling of holes in the rock or ore in order that the dynamite or powder used in blasting may be so placed as to obtain the best results. They are in direct competition with hand drilling and, except in prospecting and exploration work, are fast superseding the older method. The requirements of such machines are that they should be mobile, that they should be able to stand the hard usage and unfavorable conditions incidental to underground work, and that they should be as mechanically efficient as is consistent with the previously named conditions. Much ingenuity has been displayed in their design, but the type which has withstood trial and has proved worthy of consideration is that actuated by compressed air. The compressed air is delivered to the machine usually under a pressure of from 70 pounds to 100 pounds per square inch, is ordinarily generated on the surface and conducted underground in pipes or cables. In the case of isolated individual units 1-1/2 in.

development work, be generated underground at a point near the machine, electricity being used as the motive power for the compressor. Air drills are all reciprocating in their action and are of two types—the piston machine, where the reciprocating piston and the drill are joined together, the drill moving backward and forward with the piston, and the hammer machines, in which the piston is of a slightly different design and is not attached to the drill, the piston taking the form of an air-actuated hammer. Drilling machines directly operated by electricity have not proven a success in ore mining, although in mining coal and in quarry work electrically operated "cutters" are widely used. The equipment for generating compressed air will be described hereafter under *Air Compression*. See DRILL.

Transport of Broken Ore.—This problem may be twofold—the haulage of the broken ore from the stopes to the shafts and the hoisting from the shaft station to the surface. The consideration of the haulage facilities to be used is a question of the tonnage to be handled in a given period of time and the length of the haul. Originally the transport of ore underground was done on men's backs, and this method is still in use in Mexico, South America, and China. The next development was the use of wheelbarrows, a method still employed by prospectors. The wheelbarrow in turn was followed by the four-wheeled car running on tracks, actuated by man power, animals, or mechanical means. The use of the mine car operated by man power is practically universal in small-tonnage mines of today. In the larger mines where considerable tonnages must be handled and where the distances to be hauled are great it becomes necessary to use a more economical motive power. To that end rope haulage, compressed-air locomotives, storage-battery locomotives, electric trolley motors, and gasoline motors have been developed. The question of a choice between these various types of machines is purely a question of economics and flexibility of service desired.

Pumping Equipment.—In practically all mines some mechanical provision must be made for removing accumulating water, and in many mines the question of handling the water is all-important. The problem of water removal is met in two ways: if the flow is light or if the operations are of a very temporary nature, the water may be removed by bailing or the use of the hoist with a special bucket; if the flow is large or if the work is of a permanent nature, pumps will be installed at suitable locations underground.

Pumps may be classed according to the character of motive power into steam driven, compressed-air driven, and electrically driven. The first two types are practically identical in design for the smaller units; those of larger capacity may be so modified as to give greater mechanical efficiency. As used underground practice indicates that steam and air driven pumps be reciprocating in action and direct connected. Electrically driven pumps, now coming into wide use, are rotary in action and connected either directly or by gears to the motor. The prime requisite of mine-pumping machinery is reliability of action, mechanical efficiency being of secondary importance.

In this connection it may be well to make mention of the Cornish pump, the first pumping

engine to handle large quantities of water successfully. Pumps of this type have been largely superseded by the types described above. There are still, however, places where it is in use and even where it is being installed. The Cornish pump consisted of a steam cylinder located near the shaft mouth, the piston being connected to and actuating a walking beam, the outboard bearing of which was directly above the pumping compartment of the shaft. Through this outboard bearing a line of timber rods passing down the shaft operated an encased plunger at the bottom. The operation of the plunger was similar to that of our deep-well pumps of to-day. On its down stroke the water barrel was filled, on its up stroke the water was lifted and forced into the water line leading to the surface, a corresponding quantity being displaced and discharged. See PUMPING MACHINERY.

Surface mechanical equipment must provide for some or all of the following operations: compression of air; hoisting; ventilation; generation of electric power.

Air compression is performed in either one or two stages in units of any size, in specially constructed machines which may be driven by any of the prime movers given. In this operation air at atmospheric pressure is taken into the compressor and compressed to pressures of from 70 pounds to 120 pounds per square inch with a proportional decrease in volume. The air so compressed is piped to the point of use—either the hoist, the pump, or the drilling machines. While it may be successfully argued that the use of a prime mover to generate compressed air which in turn is used to actuate other machinery is accompanied with a loss in efficiency, yet the conditions under which mine machinery must work more than offset this apparent lack in economy. The transmission of compressed air over long distances does not result in transmission losses as high as would be the case were steam piped under similar conditions. Furthermore, in underground workings it would be impossible to allow steam to exhaust into the air, while on the contrary an air exhaust is a benefit. See AIR COMPRESSOR.

Hoisting.—In those mines worked through shafts provision must be made for elevating the ore and men to the surface and for lowering men and supplies. This function is performed by machines variously known as hoisting engines, hoists, or winding engines. These engines, usually located near the shaft collar, consist of a drum or reel which may be rotated by means of a steam engine, a compressed-air engine, an electric motor, or a gasoline engine; the engine and drum are erected on the same bedplate, the driving power of the engine or motor being applied either by direct connection, gears, or friction drives. The rotation of the drum or reel winds or unwinds a wire cable which, passing over a sheave wheel supported on a suitable framework, variously known as a head gear, head frame, or gallow's frame, directly above the shaft collar, is connected to the carrying receptacle (skip, cage, or bucket) and raises or lowers it at will. The whole operation is analogous to the use of elevators in our present high buildings.

Ventilation.—The problem of providing quantities of fresh air to underground workings has been a very essential part of the development of the coal-mining business. In the smaller metal mines, however, dependence is had on natural

ventilation, except possibly in isolated workings, and upon the exhaust from air drills and pumps. In the larger ore mines, and especially in those in which sulphide ores are found, the present practice is to follow the lead of the coal miner and mechanically to force ventilation, it having been demonstrated that the efficiency of the workman is increased if he has an adequate supply of good air. The blowers used are usually located close to the shaft collar or mine entrance, and are operated, either by direct connection or through gears or belts, by any convenient form of motor. These blowers are employed either to blow air into the workings or to exhaust air from them. They consist of a rotary fan incased in sheet metal and connected with the mine workings by large-diameter sheet-metal pipes. In the case of positive blowers the air taken in by suction at the centre of the fan is discharged at the periphery at a slight pressure into the pipe, which conducts it underground, usually to the lower workings, where it is discharged, the vitiated air being forced upward and out through the shafts or raises. Suction fans operate in the reverse manner, the vitiated air being taken into and carried to the surface through the pipes, while its place is taken by fresh air entering at the shaft collar.

Electric Power.—As has been indicated, electricity as a motive power for mining machinery has a wide range of usefulness. Perhaps the one factor which more than any other has caused its wide use is the ease, efficiency, and cheapness with which it may be conveyed from the point of generation to the place of use. The production of the electric power in the first place is a function of the surface mechanical equipment. The type of generating machine or dynamo will depend on the character of the current desired, which in turn is determined by the use to which it is to be put.

Closely associated with the surface mechanical equipment above described are the shops which must be provided for the repair and maintenance of the mechanical plant. The magnitude and equipment of these shops will depend upon the size of the mine and upon its distance from supply centres. In any event there must be provided a blacksmith shop, whose function it is to sharpen and maintain drills used underground, be they hand or machine. The normal small mine ordinarily has a combination blacksmith and machine shop, whose equipment will include a drill press and small lathe, in addition to a drill-sharpening and blacksmithing outfit.

Organization. The active life history of any mineral deposit can be divided into two periods—that of exploration and development and that of working or operating. During the first period there should be employed a consulting engineer to advise regarding the potential resources of the deposit and to outline the scheme of exploration and development to be followed. The man chosen for this work should have a thorough knowledge of mining geology, of practical mine management, and should have common sense. Needless to say he must be honest. The requirements are such that it is safe to say that no man with less than 10 years' active mining experience is likely to qualify. Under the direction of the consulting engineer will be the field manager or superintendent, whose chief qualifications should be getting work done under any and all conditions cheaply and quickly. On small operations he will probably act as his own

bookkeeper, chemist, and surveyor. Under the superintendent will be foremen and shift bosses, who are directly in charge of the various squads of workmen.

During the operating or working period the organization will be divided into departments as follows: mining, mechanical, chemical, engineering, clerical, and metallurgical. The heads of each department report to the superintendent. It may be that on small properties the chemical and engineering departments will be merged and will be represented on the pay roll by one man or two men only. On such a property it is probable that the mechanical department would consist of not more than three or four men. On the other hand, large properties naturally mean enlarged departments with superintendents and foremen in each. Whether the work be large or small, it is imperative that there shall be an absolute placing of authority and responsibility.

Economics. Good business principles should apply to mining, although this does not seem to be realized by most business men investing in and operating mines. To use an analogy, a mineral deposit should be likened to a manufacturing enterprise in which the quantity of raw material is limited. If looked upon in this light there immediately present themselves three main items for consideration: (1) the sale value of the possible product; (2) the cost of production; and (3) the capital investment needed. The first item, the sale value of the product, requires an inquiry into what is a fair average selling price and what is the breadth of the market. The second, the cost of production, requires a special knowledge of mine and metallurgical operations and is best answered by specialists in the business and by inquiry as to what other people have done under like conditions. The third, or capital investment required, should likewise be answered by a specialist. With these three considerations investigated and answered it is a simple problem to figure the net returns to be expected, both annually and in total, and, applying this to the capital investment called for, to figure a percentage return on money invested. It should be remembered, however, that the profits resultant from mining investments must provide not only for interest on money expended but also for amortization of the investment itself within the life of the mine. Unfortunately the average mining investor misses this last point and forgets entirely that his dividend has such a twofold nature. It is because of this fact that the dividends paid or anticipated from an investment in a mining enterprise, in order to be at all attractive, must be greater than those paid by other industrials.

The question of what constitutes a proper and attractive return on such investments necessitates a consideration of the chances to be taken, which chances are dependent upon the degree of development and upon the geological and mineralogical character of the mineral deposit. Based on their degree of development, mining properties may be broadly classed under two headings—prospects, or properties showing little or no ore developed, and mines, or properties having developed ore. In the first class, or prospects, it will be seen that any investment therein must be considered as purely speculative, for not only are the possible profits from the working of the ore, should it be found, a matter of estimate, but also the finding of ore in com-

mercial quantities is problematical. The only safeguards for such a speculative investment are the recommendation of an honest and able mining engineer, the assurance that sufficient cash has been raised to carry out development work as outlined, and that the management be honest and efficient. To assume such chances the investor is warranted in insisting that possible profits should be several times his investment.

In the second class, or mines, the question of a proper return on money invested is dependent on the size of the deposit and the character of the ore. In the case of some of the larger mining companies operating extensive deposits of iron, copper, lead, or gold ores where the life of the deposits can be safely calculated to run for many years, the elements of chance incidental to mining are so far eliminated that the investor would be justified in investing on the basis of 10 per cent annual profit in addition to the return of his capital within the life of the mine. In those companies operating mines where the ore bodies are small, as is the case in most of the precious-metal mines, and "where the profit in sight (the only guarantee in mine investment) is below the price of investment, the percentage of annual return should increase in proportion."

In any event the prospective investor should have submitted to him a written or printed statement covering the following points: name of company or property; location of holdings; area and character of holdings; status of ownership; classification of property, whether a prospect or a mine; character of product. In addition to the above general data there should be submitted, if the property is a prospect, the recommendations of a reliable engineer both as to the possible future of the property and the probable expenditures necessary for exploration and development work. If the property is a mine the statement of the engineer should indicate the amount and character of development work done; the amount and value of the ore developed; the operating costs, either as at present or as estimated; the justified working scale; the life of the developed ore; the probable total and annual profits; and the possibility of finding additional ore. In the case of the owner being a corporation a formal financial statement should be made.

With this information in hand the possible investor is in a position to form some opinion himself regarding the merits of the proposition and intelligently to seek advice of his own engineer, who will advise as to whether or not the purchase should be made, an option taken, or the proposition turned down, as the case may require.

MINING ENGINEERS, AMERICAN INSTITUTE OF. A society founded in 1871 for the promotion of the arts and sciences connected with the economical production of minerals and metals, the discussion of professional papers, and the circulation of information connected with mining interests. It had a membership at the beginning of 1915 of over 5000, made up of honorary, elected, and associate members. The annual meeting of the institute is held in February, with other meetings during the year as authorized by the council. The institute publishes three volumes of *Transactions* annually and a monthly *Bulletin* which appears on the first of each month. The headquarters of the institute are in the Engineering Building in New York City.

MINING LOCOMOTIVES. See ELECTRIC RAILWAYS; LOCOMOTIVE; COMPRESSED-AIR LOCOMOTIVE; STEAM ENGINE.

MINISTER (Lat., servant). A public functionary who has the chief direction of any department in a state government. (See MINISTRY.) Also the delegate or representative of a sovereign at a foreign court to treat of affairs of state. Every independent state has a right to send public ministers to any other sovereign state with which it desires to preserve relations of amity. Semisovereign states have generally been considered not to possess the *jus legationis* unless when delegated to them by the state on which they are dependent. The right of confederated states to send public ministers to each other, or to foreign states, depends on the nature and constitution of the union by which they are bound together. The constitution of the United Provinces of the Low Countries and of the old German Empire preserved this right to the individual states or princes, as do the present constitutions of the German Empire and Swiss Confederation. The Constitution of the United States either greatly modifies or entirely takes away the *jus legationis* of the individual States. Every sovereign state has a right to receive public ministers from other powers, unless where obligations to the contrary have been entered into by treaty. Diplomatic usage recognizes four orders of public ministers. These, as defined by the Congress of Vienna (1815), supplemented by that of Aix-la-Chapelle (1818), are the following: (1) ambassadors and papal legates or nuncios; (2) envoys and

ministers accredited to sovereigns; (3) ministers resident; (4) *chargés d'affaires*. Ministers of the first order possess the representative character in the highest degree, representing the state or sovereign sending them not only in the particular affairs with which they are charged, but in all other matters of state; they may claim the same honors as would be accorded their sovereigns if present in person. A principle of reciprocity is recognized in the class of diplomatic agents sent. States enjoying the honors of royalty send to each other ministers of the first class; so also in some cases do those states which do not enjoy them; but it is said that no state not possessed of such honors is entitled as matter of right to the acceptance by a royal or Imperial state of a minister of the first class.

Besides these orders of ministers there are other diplomatic agents occasionally recognized—as deputies sent to a congress or confederacy of states and commissioners sent to settle territorial limits or disputes concerning jurisdiction. These are generally considered to enjoy the privileges of ministers of the second and third orders. Ministers mediators are ministers sent by two powers between which a dispute has arisen to a foreign court or congress where a third power, or several powers, have, with the consent of the two powers at variance, offered to mediate between them.

Ministers sent to a congress or diet have usually no credentials, but merely a full power, of which an authenticated copy is delivered into the hands of a directing minister, or minister mediator.

The title "excellency" has since the peace of Westphalia been accorded to all diplomatic agents of the first class; and in some courts it is extended to ministers of the second class, or at least to those sent by the Great Powers.

By the American system ministers to exercise diplomatic functions at foreign courts are appointed by the President and confirmed by the Senate. See AMBASSADOR; ENVOY; CONSUL, MERCANTILE; DIPLOMACY; DIPLOMATIC AGENTS; INVIOABILITY. See also CABINET. Consult the authorities referred to under the last three of these titles.

MINISTERIAL OFFICER. An officer whose functions consist in executing the command of a superior, or in performing a duty definitely prescribed by law. Its propriety is not left to his judgment or discretion. He is legally bound to perform it; and for a failure to do his duty he is liable in damages to the person in whose favor the duty was to be discharged. A policeman, sheriff, or marshal having a writ for the arrest of a designated person is liable for false imprisonment if he arrests any other person than the one named. Or, he may have arrested the wrong person because of mistaken information, yet having acted with due caution in making his inquiries. In both cases he is liable. As a rule the ministerial officer acts at his peril. Perhaps the harshest application of this rule is seen when he enforces legal process under an unconstitutional statute. If, on appeal, the statute is declared unconstitutional by the highest court of the state, the judges of the lower court are not civilly responsible for their blunder, but the sheriff who seized and sold property under the execution must respond to the owner for its value.

Ofentimes a judicial officer or a legislative

body is required to act in a ministerial or executive capacity. Generally speaking, a judge acts ministerially when an application for a writ of *habeas corpus* is made to him. The law does not leave the granting or withholding of this writ to his discretion. A justice of the peace who has rendered judgment in a case before him is under a peremptory duty to issue an execution thereon at the request of the judgment creditor. In issuing or refusing it he acts ministerially, not judicially. If a statute charges a county judge with the duty of selecting jurors for the various courts sitting in the county, his acts under the statute are ministerial. Whether an act required by law of an officer is judicial or ministerial depends upon its character, and not on the rank of the actor. See OFFICER, and the articles there referred to.

MINISTER'S WOOING, THE. A story by Harriet Beecher Stowe, published as a serial in the *Atlantic Monthly* (1859).

MINISTRY. A body consisting usually of the heads of the chief executive or administrative departments of a government, and constituting an advisory council of the sovereign. In several European countries there is a chief minister who has a certain precedence in rank and authority over his colleagues and who is known as the premier or prime minister. In several others the chief minister bears the title of minister president and enjoys a certain precedence in dignity over his colleagues, but exercises no authority over them. Everywhere the right of selecting the members of the ministry belongs to the chief executive. In those countries, like England, where the crown is only the nominal executive, the head of the state selects only the prime minister and intrusts the selection of the others to him. In the German Empire, the Kingdom of Prussia, the Empire of Japan, and the American republics, where the ministers are not responsible to the legislature for their political policy, they are all appointed directly by the chief executive without being restricted to acknowledged party leaders. It is a general rule in European countries that members of Parliament may, with the approval of their constituents, serve as ministers. But, whether members of Parliament or not, ministers are entitled to sit in either House and to participate freely in the discussion of measures in which they are interested.

In general, the term "ministry" is synonymous with the term "cabinet" (q.v.), but there are exceptions. Thus, in Great Britain, the ministry includes, in addition to members of the cabinet, all those political undersecretaries who have seats in Parliament (at present about 40 in number) and who are expected to resign when their policy is defeated in the House of Commons; while the cabinet consists of a certain number of ministers (22 in 1915) who control the policy of the government and preside over the chief administrative departments. Thus it will be seen that not all the ministers are members of the cabinet. On the other hand, it may happen that some members of the cabinet will have no administrative duties. Such members are known as ministers without portfolios. Departments of administration over which ministers are generally placed are: foreign affairs, war, finance, justice, public education, public worship, navy, commerce, post and telegraphs, and colonies. In those countries where ministers are responsible to the chief executive they

act independently of one another in the conduct of their administrative departments, and their responsibility is individual rather than collective.

MINITARI, *mé'né-tá'rè*, or **HIDATSA**, *hédit'sá*. A tribe of Siouan stock (q.v.), closely related to the Crow (q.v.). Since known to the whites they have resided nearly in their present position on the Missouri River in North Dakota in close alliance with the Mandan and Arikara (q.v.). They call themselves Hidatsa, their popular name being of Sioux or Mandan origin and said to signify "people who have crossed over the water." Both they and a detached band of Arapaho were known to the French as Gros Ventres (q.v.). They occupied permanent stockaded villages of circular earth-covered log houses along the bluffs of the Missouri, where they had fields of corn, pumpkins, and sunflowers and made periodic excursions into the open plains to hunt the buffalo, at which times they lived in tepees. Like their allied tribes, they had elaborate ceremonies and social organization. They have been uniformly friendly to the whites. In 1804 they were estimated at 2500, but have decreased rapidly, first from the smallpox of 1837 and later from the diminished food supply consequent upon the destruction of the buffalo. They number now about 547 and live with the Mandan and Arikara upon the reservation at Fort Berthold. Consult Washington Matthews, *Ethnology and Philology of the Hidatsa Indians* (Washington, 1877), and R. H. Lowie, "Societies of the Crow, Hidatsa, and Mandan Indians," in *American Museum of Natural History, Anthropological Papers*, vol. xi (New York, 1913).

MINIUM, or **RED LEAD**. A beautifully scarlet crystalline substance consisting chiefly of lead orthoplumbate, $2\text{PbO}:\text{PbO}_2$. It is made by cautiously heating massicot or white lead in a reverberatory furnace or in special barrel-shaped ovens open at both ends. If heated, minium gradually changes its color, becoming violet and ultimately black; but it regains its original color on cooling. If ignited in the air, minium is converted into the monoxide of lead. Minium is used as a mineral color, yielding a fine paint. It is also employed in the manufacture of flint glass. See **LEAD**.

MINIUS. The Roman name for the river Miño.

MINIVET. One of a group of about 20 species of small shrike-like birds of the Oriental region. The males are, in general, black and rose, while the females are gray and saffron. Consult Blythe, *Mammals and Birds of Burma* (London, 1875), and other authorities on Oriental ornithology cited under **BIRD**.

MINK (probably from Swed. *månk*, mink). Any of several species of weasel-like animals of the genus *Putorius*, family Mustelidae, distinguished from the martens, stoats, etc., by their semiaquatic habits and certain peculiarities of dentition. Very recently *Putorius* has been considered as a subgenus of *Mustela*. The American mink (*Putorius vison*) is found throughout North America, but especially in the northern and mountainous parts. The European mink (*Putorius lutreola*), usually called *norz* or *månk*, occurs in Finland, Poland, Scandinavia, and Russia and formerly extended as far west as central Germany. The mink of Siberia (*Putorius sibirica*) is a quite distinct but little-known species. The American mink is somewhat larger than the European species (15 to 18 inches long, besides the tail, 9 inches) and is

further distinguished by the black upper lip; in the European mink the upper lip is white.

Minks are inhabitants of well-watered areas, haunting the banks of streams and borders of ponds in search of their food and making their homes in burrows which open near the water. They are excellent swimmers, having the feet partially webbed, and spend much time in the water. Although, like other Mustelidae, they eat birds, small mammals, and eggs, the principal food of minks comes from the water: thus, fish, frogs, salamanders, crayfish, and even mollusks form their chief diet, and muskrats and other water-loving mammals also fall prey to their voracity. The fur of the mink is of great value commercially, though the price varies much with color and quality. (See **FUR AND THE FUR TRADE**.) Minks are usually brown, sometimes rather light, but more often very dark, especially along the middorsal line. The darker the animal the more valuable it is. The fur is made up of a dense undercoat and an outer coat of long, shining hairs, and the skins from the coldest regions are usually the most valuable. Like all its near relatives, the mink is bloodthirsty and cruel. It is very courageous, and when cornered is savage. The young are born in the early spring, usually in a hole in the bank of some body of water, where plenty of food is easily obtained. The number of young is about six in a litter. The mink is second only to the skunk in the strength, penetrating power, and nauseousness of the odor of the secretion in the anal glands, but fortunately it is only when the animal is greatly enraged that the odor becomes very disagreeable. Minks are said to be easily tamed if taken young, and to enjoy being petted, but their temper is capricious, and as they grow old they become dangerous. Civilization seems to have little effect upon them, there being few districts so completely cleared or densely settled as not to afford them some sort of refuge.

Consult: Audubon and Bachman, *Quadrupeds of North America* (New York, 1851); Elliott Coues, *Fur-Bearing Animals* (Washington, 1879); Stone and Cram, *American Animals* (New York, 1902); E. T. Seton, *Life-Histories of Northern Animals* (ib., 1909); Ned Hollister, "A Synopsis of the American Minks," in *United States National Museum, Proceedings*, vol. xlv (Washington, 1913). See **FUR-BEARING ANIMALS**.

MINK FROG, **HOOSIER FROG**, or **NORTHERN FROG**. A small frog (*Rana septentrionalis*) of the northwestern United States. It is $2\frac{1}{4}$ inches long from nose to vent, dark olive green above, with sooty-brown bars and blotches, and pure white underneath. Its hazel iris, minky color, and quiet solitary habits distinguish it from others. A detailed account of its features and ecology was given by J. H. Garner in the *American Naturalist*, vol. xvii (Philadelphia, 1883).

MINIKOPIS. The inhabitants of the Andaman Islands. See **MINICOPIES**.

MINKOWSKI, *mín-kóf'ski*, **HERMANN** (1864-1909). A mathematician, born at Alexoten, Russia, but a resident of Germany. He was educated at the universities of Berlin and Königsberg (Ph.D., 1885) and served as a lecturer (1887-93) and assistant professor of mathematics (1893-94) at Bonn and as professor of mathematics at Königsberg (1894-96), at the Zurich Polytechnic (1896-1902), and at Göttingen (1902-09). His publications include: *Geometrie der Zahlen* (1896); *Diophantische Approximationen* (1907); *Über die*

tionen, eine Einführung in die Zahlentheorie (1907); *Gesammelte Abhandlungen* (1911).

MINNA VON BARNHELM, min'nå fån bårn'hëlm. A comedy by Lessing, produced at Hamburg in 1767.

MINNEAPOLIS. A city and the county seat of Ottawa Co., Kans., 128 miles by rail west of Topeka, on the Solomon River and on the Union Pacific and the Atchison, Topeka, and Santa Fe railroads (Map: Kansas, E 4). It derives considerable trade from the adjacent farming and stock-raising country and has grain elevators, flour mills, carriage shops, a foundry, etc. Building stone is quarried in the vicinity. There are a public-school library and municipally owned water works. Pop., 1900, 1727; 1910, 1895.

MINNEAPOLIS. The largest city of the State of Minnesota and the county seat of Hennepin County, situated at the Falls of St. Anthony, on the Mississippi River, above St. Paul, the suburbs of which join those of Minneapolis, the two municipalities being termed Twin Cities (Map: Minnesota, D 6). The river, which divides the city into unequal portions, the main portion being on the right bank, is crossed by a number of massive highway and railroad bridges. The Falls of St. Anthony are in the heart of the manufacturing district.

Minneapolis stands on a gently undulating plateau, 800 feet above sea level, in a picturesque lake region much frequented as a place of resort. There are several lakes within the city limits, and of others in the immediate vicinity, Lake Minnetonka is the largest and most popular. The city is about 10 miles long by 6 in width and has an area of 53 square miles. Its streets are broad and regular. An extensive park system (3783 acres) has been developed, embracing several lakes, 50 parks, and 50 miles of parkway, almost all of which are skirted by a wide boulevard known as the Grand Rounds. Of particular note are Kenwood Boulevard (150 feet wide), Loring and Gateway parks, in the centre of the city, and Minnehaha Park, containing the Falls of Minnehaha, 50 feet in height. Adjoining the park are the beautiful grounds of the State Soldiers Home. Minneapolis has many handsome public and business edifices, besides a number of attractive churches. Among these are the cathedrals of the Immaculate Conception and St. Mark; Central High School; Minneapolis Institute of Arts; the county courthouse and city hall building, erected in 1900 at a cost of \$3,500,000 and offering from its main tower, 345 feet high, a superb view of the city; the public library and post office, both fine Romanesque structures; Raddison, Dyckman, and Andrews hotels; and the Plymouth, Andrus, Palace, McKnight, Security Bank, and Soo First National Bank buildings.

Commerce and Industry. The conditions which have contributed most to the industrial development of Minneapolis are the advantages afforded by the Falls of St. Anthony and their convenient location in relation to the abundant grain and timber of the Northwest. Excellent transportation facilities give the city command over these supplies and over the markets of the country, its jobbing trade in 1914 having amounted to about \$300,000,000. Twenty-two lines of railway, operated under 10 systems, enter the city, and a complete system of inter-urban electric lines has been effected. With these advantages Minneapolis has developed

into the foremost city of the Northwest, being noted particularly for its manufacturing and wholesale interests. The first manufactory in the State was established at the Falls of St. Anthony. It was used first as a saw mill and then as a flour mill. The power afforded by the Falls has been utilized more and more, until Minneapolis has become the largest flour and lumber market in the world. The water power at the Falls of St. Anthony was developed, previous to 1879, to yield 30,000 horse power, and in 1897 a new dam, giving 10,000 horse power, was completed. The United States government is (1915) constructing a system of locks and dams below the Falls which will add 40,000 horse power and which will place Minneapolis at the head of navigation. For a number of years the lumber industry was most important, but after the introduction of improved processes of flour milling in the seventies, the latter industry surpassed lumber manufacturing and has since rapidly outstripped it. The flour mills in the Falls district are now the largest in the world. The value of their output in 1905 was \$62,700,000, while in 1914 this was increased to \$90,000,000. Lumber products worth \$12,000,000 were made in the same year, and an equal value each of machinery, linseed oil and meal, and food and clothing. Other manufactures brought the total value of the city's industrial output in 1914 to \$165,000,000, on an invested capital of \$90,000,000. Minneapolis was the first city in the United States definitely to plan a combined factory and residence district wherein industries are guaranteed the trackage and transfer facilities that they need and where workmen may make their homes among natural woods and gardens. In 1914 there were received in the city 200,000,000 bushels of grain, of which 90,000,000 were wheat. Fifty elevators, with a capacity of 40,000,000 bushels, stored and cleaned this grain.

Finance. According to the Minnesota law, assessment is made on a 40 per cent valuation. The assessed valuation of the city in 1914 was \$196,303,280. This, at a rate of 35.77 mills, yielded a revenue of \$6,644,866.08. Of this amount there was spent: for schools, \$2,037,831; for police and fire protection, \$1,019,000; for interest on debt, \$850,000. The city owns and operates its water works, which, with a recently installed filtration plant, are valued at \$1,500,000. Another municipal enterprise is a garbage consumer, from which enough current is obtained to light a considerable portion of the city. The bonded indebtedness is \$22,237,200, offset by a sinking fund of \$4,087,203 for the retirement of bonds. The city is the home of the Federal reserve bank for the ninth district. Its 25 banks have a capital of \$8,000,000 and a total deposit of \$120,000,000.

Education. Minneapolis sends 50,000 children to the public schools, and of these 6000 are in the five high schools. The city is cooperating with the Dunwoody Institute, a vocational school for boys, and is itself conducting a similar school for girls. The University of Minnesota (q.v.) is situated here, while other institutions include Stanley Hall, Graham Hall, and St. Margaret's Academy, for girls; Blake School and De La Salle Institute, for boys; Augsburg Seminary (Lutheran), Minnesota College; the Johnson School of Music and the Northwestern Conservatory of Music; the Handicraft Guild and the Minneapolis School of Fine Arts. More than 10,000 pupils attend these schools and the

nine commercial colleges. There is a public library, with 290,000 volumes for circulation from its main building and from 35 branches and stations.

Within the last 10 years the city has made wonderful progress in the arts. The Minneapolis Symphony Orchestra (q.v.) is recognized as one of the best organizations of its kind in America, and the Minneapolis Institute of Arts, dedicated in 1915, together with the private gallery of T. B. Walker, makes the city conspicuous as a music and art centre. The interest in music is manifest in the many choral and orchestral clubs, and the interest in art in the fine sculptural works to be seen in different parts of the city. Notable among these are French's statue of Governor Pillsbury, on the university grounds, and Jacob Fjelde's figure of Ole Bull, in Loring Park, and of Hiawatha, in Minnehaha Park.

Government. Minneapolis is governed under what is known as the Federal plan. A council, consisting of two aldermen from each of the 13 wards, legislates. Its powers, however, are limited by the State to such an extent that the city has endeavored to secure a new charter that will give home rule and result in greater efficiency. The mayor, treasurer, and comptroller are the executive officers. The mayor is in charge of the police. He has the power of veto on all council measures, subject to the usual two-thirds overruling vote. In addition to these officers there are the school, park, and library boards, the members of which are elected; a board of corrections and charities, consisting of the mayor and four of his appointees; and the board of tax levy, composed of the mayor, the presidents of the council, school, park, and library boards, and one county commissioner. This board meets each year to determine the rate. Two elected judges preside over the municipal court. Elections are held biennially. A civil-service commission examines applicants for positions in city offices and on city works. Other special features of the government are the patrol-limits system, by which saloons are confined to a small area in the centre of the city, and a public-morals board, which advises the mayor and the council as to the moral condition of the city.

History. The first white man known to have visited the site of Minneapolis was Father Hennepin. In August of 1680, while on his way to rejoin La Salle, he passed the falls and named them St. Anthony. Various French fur traders followed Hennepin, and Jonathan Carver (q.v.) in 1766 made a journey up the Mississippi and Minnesota rivers. Upon his return he published a glowing account of the country, emphasizing its "exceeding beauty" and its great commercial possibilities. In 1805-06 Lieut. Zebulon Pike was sent into the country of the Sioux to induce them to make peace with the Chippewas and to assert the right of the United States against that of the English traders established on the upper Mississippi. In the treaty that Pike concluded with the Sioux was a clause ceding to the United States a strip of territory extending from the confluence of the Mississippi and Minnesota rivers northward for 9 miles on each bank of the Mississippi. This included the Falls of St. Anthony and the site of Minneapolis. In 1819 the United States government, following the suggestion of Major Long and in compliance with the request of the Astor fur interests, sent Colonel Leavenworth to build a fort at the mouth

of the Minnesota. Leavenworth's successor, Col. Josiah Snelling, placed the fort, named for him, on the near-by bluff. In 1823 the government built a mill (where a great mill now stands) for the manufacture of lumber and flour for the fort. Before the land on the east bank of the river had been opened to settlement several of the fort's officers had squatted on claims from which they proposed to control the water-power rights. Franklin Steele held the choice site in 1848, when settlement was legalized. He platted a village, St. Anthony, in that year and built the first commercial saw mill. Maine lumbermen soon hurried to the new village, and it grew rapidly. Shortly afterward a university was established. Like the soldiers, however, the newcomers squatted on government land embraced in the Fort Snelling reservation on the west bank of the Mississippi. Col. John Stevens, holding for Steele a claim facing his town site, built the first house in Minneapolis proper in 1850, on the site of the Union Station. Before the claims were legalized in 1855 a village of considerable importance had developed, but after that date it grew more rapidly than St. Anthony. The settlement, having previously borne several names in succession, was incorporated in 1856 as the town and in 1867 as the city of Minneapolis. In 1872 the city of St. Anthony, directly across the river, which had been settled in 1837 and incorporated in 1855, was annexed. After 1860 the growth of the city was exceedingly rapid. From 1886 to 1893 a large Industrial Exposition was held here, and in 1892 the Republican National Convention met in the Exposition Building. Pop., 1870, 13,066; 1880, 46,887; 1890, 164,738; 1900, 202,718; 1910, 301,408, including 85,938 persons of foreign birth; 1914 (U. S. est.), 343,466; 1920, 380,582. Consult: Isaac Atwater, *History of the City of Minneapolis* (New York, 1893); W. W. Folwell, *Minnesota, the North Star State* (Boston, 1908); H. B. Hudson, *A Half Century of Minneapolis* (Minneapolis, 1910); E. Dudley Parsons, *The Story of Minneapolis* (Minneapolis, 1913).

MINNEAPOLIS SYMPHONY ORCHESTRA. In 1903 a number of music lovers of Minneapolis formed the Orchestral Association of Minneapolis. Having raised a guarantee fund of \$10,000, they established the Minneapolis Symphony Orchestra of 60 performers, with Emil Oberhoffer as conductor. Immediately the organization took its place among the foremost symphony orchestras of the United States, and a new fund was subscribed for five years. In 1915 the guarantee fund amounted to \$65,000. The number of players was gradually increased from 60 to 90, Mr. Oberhoffer being retained all the time as conductor. At present the orchestra plays about 40 concerts a season in its home town and an average of 130 concerts on tours extending all over the United States. It owns an extensive library.

MIN'NEDO'SA. The chief town of Marquette electoral division, Manitoba, Canada, on Little Saskatchewan River and on the Canadian Pacific Railway, 125 miles west-northwest (direct) of Winnipeg (Map: Manitoba, C 3). Its industrial establishments include five grain elevators, three lumber yards, and a sash and door factory. The town has an electric-light and telephone system. Pop., 1901, 1052; 1911, 1483; 1915 (local est.), 2000.

MINNEHaha, min'né-há'há. The heroine of Longfellow's Indian poem, *Hiawatha*, who is

represented as the daughter of an old arrow maker. The name Minnehaha (Sioux *Mini-haha*, curling water) is borne by a picturesque cascade, about 50 feet high, in the Minnehaha River, a small stream emptying into the Mississippi at Minneapolis, Minn. It may be mentioned that in Longfellow's work the hero has an Iroquois name, the heroine a Sioux name, while the poem itself is based upon the Ojibwa legends published in Schoolcraft's *Algie Researches*.

MIN'NESING'ER. The common name for mediæval German lyric poets, preceding the *meistersinger* (q.v.), and especially for German court lyrists of the twelfth and thirteenth centuries, because their principal theme was *minne*, or love. Among other subjects of minnesong were nature, religion, patriotism, politics, and homage to princely patrons. Heinrich von Veldeke (q.v.), one of the earliest minnesingers, was also an epic poet. Minne poetry has three epochs. In the first, a little after 1150, with Der von Kürenberc as its earliest-named poet, lyric poetry begins to free itself from the epic; the second is its brilliant period, with Walther von der Vogelweide (q.v.) as its most brilliant example; the third, beginning about 1300, with Oswald von Wolkenstein as its last representative, marks its decline and the rise of the *meistergesang*, cultivated by the *meistersinger* (q.v.). The metrical form of these lyrics was at first simple, though somewhat varied, with rhyme and, with decreasing frequency, assonance. Der von Kürenberc's four-line stanza with one extra beat in the last half line became so popular on the Danube that it was adopted by the writers of the *Nibelungenlied* (q.v.). Under French influence the form became more artificial. Each minnesinger felt a proprietorship in such metrical forms as he had originated. The ditties of early singers such as Dietmar von Aist, Der von Kürenberc, Meinloh von Seveningen, and the burgraves of Regensburg and Rietenburg are marked by simplicity of thought and by absence of reaping. The minnesingers, like the troubadours (q.v.), thrived in the heyday of chivalry. How deeply each of the minnesingers was influenced by the troubadours, and to what degree they drew upon the traditions and customs of their own land, or finally to what extent they imitated once genuine emotions or spoke from their hearts, is often extremely problematical. Certainly the oldest poems utter true experience and represent the lover as wooing with ardor but proud self-respect; but later, under Provençal influence, he appears as the cringing vassal of his lady love. Some of the most ancient German poems are put into woman's mouth, but we can scarcely conclude that women were therefore among the minnesingers, though several ladies, as, e.g., the Countess of Dia, wrote love poems in Provençal.

With the more artful verses of the Burgrave Rietenburg, Provençal influence becomes clear. To all people *minne* meant love, but to the lordlier poets or to those who sang in their halls *minne* had an exalted significance. The older and far more genuine sentiment between men and women becomes either Platonic affection or sensual desire. We shall find that the minnesingers were merely doing what had been done a little sooner by the troubadours, but the minnesong was not so brilliant, though it was almost as artificial as the poems written in the best period (1100-1260) of Provençal literature (q.v.). The Germans cultivated such forms as were popular in southern France, as the love poem proper, the

serventes (q.v.), and the *tenzon* (q.v.). Like the troubadour, the minnesinger sang the praises of his lady, who was often his patron's wife. Of her he made an earthly angel, and whatsoever boon she might grant him was his bliss. The minnesingers whose dialect puts them on the western boundary of Germany first show French influence. Provençal influence is earliest perceptible in Friedrich von Hausen, a Franconian from the Rhine. The dactylic rhythm bears witness also to a romantic origin. Minnesingers who used it were, besides Friedrich von Hausen, Heinrich von Veldeke, Heinrich von Morungen, Hartmann von Aue, Walther von der Vogelweide, Hildbold von Schwangau, and Ulrich von Liechtenstein.

With Friedrich von Hausen we first meet the Crusading song. Walther von der Vogelweide gave the fullest utterance to the minnesong. In him we find both courtly and popular elements. Walther also modeled poems after romantic patterns. Austria was the centre of court poetry. There Reinmar had lived and there Walther had learned his art. Neidhart had first composed for peasants songs and dances, but his ambitious tendencies displeased them and he turned to the court. With Walther and Neidhart the road goes in twain, and each had his followers. Princes had been among the troubadours. So it was in Germany, where Henry VI and Conradin were singing in the south, while farther north were Duke Henry II of Anhalt, Margrave Otho IV of Brandenburg, and Henry III of Meissen.

The most important manuscripts are the Weingarten, the small and the large Heidelberg collections. The last contains 7000 strophes from 140 poets.

Jahrhunderts* (Stuttgart, 1891-95), and K. F. Bartsch, *Deutsche Liederdichter des 12. bis 14. Jahrhunderts* (3d ed., ib., 1893).

MIN'NESOTA. One of the North Central States of the American Union. It lies around the headwaters of the Mississippi River, between lat. 43° 30' and 49° 25' N. and long. 89° 29' and 97° 5' W. It is bounded on the north by the Canadian provinces of Ontario and Manitoba, on the east by Lake Superior and the State of Wisconsin, on the south by Iowa, and on the west by the Dakotas. It has an extreme length north and south of about 400 miles, and east and west of 380 miles, but its average width is only 240 miles. It comprises an area of 84,682 square miles, of which 3324 square miles are water. It ranks tenth in size among the States. The capital is St. Paul.

Topography. Minnesota may be said to be divided into three areas which slightly overlap. First, the highland district, which is popularly known as the Height of Land, 1750 feet above sea level, which slopes off in all directions, thus forming the watershed for three great river systems—the Red, the St. Lawrence, and the Mississippi. These highlands include the famous Vermilion, Mesaba, and Cuyuna iron ranges, and are covered with dense forests of pine, hemlock, spruce, and other evergreens, which originally extended southward to within 25 miles of the twin cities, but were terminated on the west by the slope of the Red River valley. Second, the hardwood belt, which fringes the west edge of the evergreen district, but spreads out on the south border to a width of 50 miles, ending in what was called by the Sioux "the Big Woods," a forest of immense maples, elms, oaks, and other varieties that the farmer has not wholly conquered after 50 years of constant cutting. The remainder of the State, including the fertile Red River valley, the counties on the upper Minnesota River, and those of the two southern tiers, is the prairie, treeless save only for the wooded slopes of the streams and the groves planted by the settlers, many of which, however, are now yielding crops of merchantable timber. In the southwest portion of this district the surface is broken by the coteaux des prairies, but these never attain any great height. The lowest parts of the State are the region around the head of Lake Superior and the southeastern section, where the land falls to a height of 600 feet; the very highest part is the Mesabi district, 2200 feet above sea level. The surface of the State shows the glacial action characteristic of the neighboring States, but has retained more of the moraine lakes, which are scattered thickly over the whole surface, whether forest or prairie land, to the total number of over 10,000.

Drainage. The three large river systems referred to provide an adequate drainage for the State, except in a limited area in the region of Red Lake, now drained artificially. The Mississippi receives as its chief tributaries the St. Croix, which makes the Minnesota-Wisconsin boundary line, and the Minnesota, besides innumerable smaller streams, before it leaves the State. Thus it drains over one-half the area. Although the Red River rises in Lake Traverse, less than 2 miles from the source of the Minnesota, and flows northward to Lake Winnipeg in Canada, it receives its chief supply from the west slope of the divide. Along the north boundary the Rainy River, fed by short streams from the Height of Land, finds its way to Lake of the Woods; and into Lake Superior pours the flood of the St. Louis River from the south slope of the divide. Although the Minnesota and Red rivers are reputed "navigable," the Mississippi is the only one of these streams that is much used commercially, except for the power that many of them furnish.

In the south the lakes are often broad and shallow. Three-fourths of them occupy hollows left in the moraines, or deposits of the glacial age, which cover the greater portion of the State. Others, such as Lakes Pepin, Traverse, Big Stone, and Rainy, are river expansions. The lakes vary in size from mere ponds to Red Lake, the area of which is 340 square miles. The other more important bodies are Leech and Winnebigoishish in the plateau region, Mille Lac,

and Minnetonka, a popular summer resort for the twin cities. Rainy Lake, on the north border, which has been made accessible to tourists since 1900, is fast becoming the most famous of resorts. In the glacial period an immense lake 700 miles wide was formed in the valley of the Red River. At first it was drained by way of the Minnesota River into the Gulf of Mexico, but as the ice disappeared the lake was drained northward into the Nelson River, leaving a wonderfully rich plain, marked on its east border by successive beach lines. Upon this plain Minnesota farmers have raised great crops of wheat for over 30 years. This ancient basin is known as Lake Agassiz.

Climate. Minnesota lies in the middle of the north temperate zone and in the geographical centre of the continent. This gives it a climate which, although subject to great extremes, maintains an average temperature that makes certain the annual production of a great diversity of grasses, vegetables, and fruits. The average temperatures for January are 15° F. at the southeast corner and 1° F. at the northwest corner. For July it is 70° F. in the south and 65° F. in the north. The temperature has risen to 100° in the shade on occasions in the past 25 years, and on occasions it has fallen to 40° below zero. These extreme temperatures never last more than a day or two at a time. The annual rainfall ranges from 20 inches in the northwest to over 30 inches in the southeast. The rainfall is characterized by a scant precipitation in the winter season and moderately heavy rains during the crop season. There is an annual snowfall of 20 inches in the southwest and nearly 80 in the extreme north. The southern counties have an average relative humidity of less than 70 per cent; the northern counties 75 per cent. The prevailing wind is west in the northern half and southwest in the southern half. Nights are always cool, tempering the heat of summer, and the air is always dry, counteracting the cold of winter. Because of this evenness of summer, as well as for the many advantages that the State offers to those seeking recreation, Minnesota has always been a favorite summer resort. Every year great numbers of campers and excursionists scatter over the State.

Soils. The soils are wholly glacial, and since the outcropping stratified rock is largely limestone, most of the soil derived from this source is very rich—a fine black loam. On the older drift in the southeastern counties, for 30 or 40 miles back from the Mississippi River, there is a coating of loess, a loam of exceptional fertility. Where the Cambrian sandstone outcrops in the east-central part of the State, considerable areas are covered with a light, sandy soil that until recently seemed not at all encouraging for agriculture; but, with improved methods of tilling and with a better understanding of the chemistry of soils, these areas are being brought under cultivation. It is in this part of Minnesota that a great part of the potato crop, which reached a total of 44,880,000 bushels in 1924, is produced. In the old land of the northeast and north-central districts there are areas almost denuded of soil, or covered with a scanty coating of granite drift. In 1914 the people voted to give the forestry board the power to reforest this land and so cause it to produce once more the pine that it has in the past abundantly borne, the only crop that it will

A B C Longitude 94° West D from 98° Greenwich E F G
90° 91° 92°
46° 45° 44° 43°

bear. In the valley of the Red River, the silts of old Lake Agassiz occur. On this is raised the immense wheat crop that annually brings to Minnesota great wealth from all parts of the world. Finally, in the Red Lake region, there are swamps, once believed to be waste land.

By drainage, however, this land is being opened to cultivation. In time, it will be likely to rival the other soils of the State in productiveness. The formation is of peat, decayed vegetable matter, underlain by clay.

Geology. The northwest corner of the State is Archean and its east-central portion was once occupied by a large island. These areas now consist of granites and gneisses, which also have been uncovered in the upper valley of the Minnesota River, where there are valuable granite quarries. Shore deposits and lava flows of the earliest age of the Huronian period outcrop in the old lands, cutting into the latter in deep tongues and bands, some of which contain iron-bearing beds of great wealth. The broad Huronian belt, extending southwestward from the Minnesota River, contains the Sioux quartzite, a most beautiful and valuable building stone, and beds of ancient red mud, changed by heat into the far-famed red pipestone used by the Indians.

The Lake Superior slope is underlain by what is known as Cambrian sandstone, or that formed during the first age of the third period; and the Ordovician rocks, the creation of which immediately followed the Cambrian, occur in the southeastern part of the State. These rocks, referred to as "St. Peter sandstone" and "Trenton limestone," make a combination that has given rise to the bluffs along this part of the Mississippi and to the Falls of St. Anthony. Silurian rocks occur in the valley of the Red River and in some of the southeastern counties, and slight deposits of the Cretaceous are found in various parts of the State. In the Pleistocene came the great ice invasion that, in three successive waves, swept over the northern part of the United States and is most largely responsible for the present surface. The State was almost entirely covered by ice by the first two of these waves, but in the third epoch two great lines of ice met at the centre of the State and flowed southward in a tongue to Iowa.

Mining. The importance of Minnesota as a mineral producer, ranking twelfth among the States, comes almost entirely from its iron mines. In its output of iron ore, Minnesota far outranks all the other States and contributes both in quantity and value considerably more than half of the iron ore produced and marketed in the United States. By far the largest part of the production is from the Mesabi Range, now the most important iron-producing district in the world. It lies entirely within Minnesota and is the youngest of the great iron ranges. It was opened in 1892 with a production in that year of less than 30,000 tons; in 1894 it produced nearly 2,000,000 tons, in 1902 over 13,000,000 tons, or nearly one-half of the total output of Lake Superior iron ore, and reached an unprecedented output in 1913 with 36,373,671 long tons. The Vermilion Range, of the older producing districts, is also entirely within the State, but its production in 1913 (1,536,115 tons) was not quite 5 per cent of the output of the Mesabi Range. Its maximum production was attained in 1902—a total of 2,057,273 tons. The iron-ore production is primarily the output

of St. Louis County, whose production approximates 75 per cent of the total output. The iron ore produced in the State in 1926 attained 40,961,361 long tons. The production of that year was valued at \$103,715,621.

Exclusive of iron ore, the value of the mineral products in 1926 was \$14,645,685. Of these less important industries, the principal products were from the quarries and clay pits, and these were all secondary in value. In 1926 the clay products, exclusive of pottery, were valued at \$1,852,566 and the stone products at \$3,746,392. The chief quarry products are granite, limestone, and sandstone, while the principal clay product is common brick, with smaller quantities of sewer pipe, fireproofing, front brick, drain tile, pottery, etc. The other commercial products are cement, occasional gems, lime, mineral waters, sand and gravel, and sand-lime brick. The total value of the mineral products in 1926 was \$118,361,306.

Agriculture. Over one-half of the entire land area is in farms, the proportion of farm land showing a gradual increase from the northern to the southern part of the State. Of an approximate land area of 51,749,120 acres in 1925, 30,059,137 acres were in farms, which numbered 188,231. The improved land in farms amounted in 1920 to 21,482,000 acres. The total value of farm property, including land, buildings, implements and machinery, domestic animals, poultry, and bees, was in 1925, \$2,761,684,227. Of the total number of farms in 1925, 137,148 were operated by owners and managers. The percentage operated by tenants is, however, steadily increasing, having been in 1880, 9.1 per cent; in 1890, 12.9 per cent; in 1900, 17.3 per cent, and in 1925, over 25 per cent. In 1925 approximately 67 per cent of the farms in Minnesota were at least 100 acres in size.

The native white farmers in 1920 numbered 110,966 and the foreign-born white farmers, 67,305. Negro and other non-white farmers numbered 207. It will be noted that Minnesota is one of the few States in which the foreign-born white farmers approach the number of the native white. Of the foreign-born farmers, a great many were born in Germany.

The following table shows the acreage, production, and value of important crops as estimated by the United States Department of Agriculture in 1927 and 1928. The total value

CROP	YEAR	ACREAGE	PROD. BU.	VALUE
Corn	1928	4,089,000	143,115,000	\$88,731,000
	1927	4,172,000	127,246,000	81,437,000
Hay	1928	4,256,000	6,558,000 *	62,590,000
	1927	4,358,000	7,906,000 *	63,241,000
Oats	1928	4,089,000	153,338,000	53,608,000
	1927	4,350,000	116,580,000	46,632,000
Wheat	1928	1,590,000	21,955,000	22,948,000
	1927	1,763,000	20,925,000	22,849,000
Barley	1928	2,000,000	60,000,000	30,000,000
	1927	1,460,000	43,800,000	28,470,000
Potatoes	1928	354,000	88,940,000	11,682,000
	1927	328,000	33,128,000	10,877,000
Flaxseed	1928	726,000	5,318,000	11,312,000
	1927	757,000	7,313,000	14,099,000
Rye	1928	462,000	5,950,000	5,068,000
	1927	383,000	7,009,000	5,958,000

* tons

of crops in 1927 was \$324,400,000. The general character of agriculture is indicated by the fact that about three-fifths of the total value of crops in recent years was contributed by the cereals and about one-fifth, by hay and forage. The remainder consisted mostly of potatoes and other vegetables and of forest products. The produc-

tion of wheat in 1909 amounted to 57,094,412 bushels, valued at \$56,007,435. The acreage devoted to this crop was 3,276,911. Oats, the second important crop, had an acreage of 2,977,258 in 1909, the production amounting to 93,897,717 bushels, valued at \$34,023,389. Corn and hay and forage came next, with productions of 67,897,051 bushels and 6,036,747 tons, valued at \$30,510,145 and \$26,724,801, respectively. The acreage was 2,004,068 and 3,946,072, respectively.

The total acreage of potatoes and other vegetables in 1909 was 269,713 and their value was \$11,044,391. Excluding potatoes, the acreage of vegetables was 46,021, their value, \$3,359,000.

The soils in several portions are adapted to the growing of apples and they are the most important of the orchard fruits produced. There were grown, in 1926, 1,230,000 bushels, valued at \$1,230,000. Orchard fruits next in importance were plums and prunes. The total value of orchard fruits in 1909 was \$801,112. In addition to this, there were grown 293,805 pounds of grapes, valued at \$11,021. The most important of the small fruits is the strawberry, of which 2,730,099 quarts, valued at \$268,772, were grown in 1909. The growing of sugar beets is an industry of some importance. There were devoted to this product, in 1909, 2238 acres and the product was 24,140 tons, valued at \$118,625.

Live Stock and Dairy Products. The total value of live stock on the farms in 1925 was \$229,976,511. The cattle on the farms on Jan. 1, 1925, according to the estimates of the United States Department of Agriculture, numbered 2,853,405 and were valued at \$109,381,396; dairy cows numbered 1,311,879; horses, 834,680, valued at \$62,292,271; sheep, 378,972, valued at \$3,381,974; swine, 2,715,074, valued at \$39,153,051; mules, 12,001, valued at \$951,217. The total value of milk, cream, and butter fat sold and butter and cheese made in 1924 was \$81,351,771. The milk sold amounted to 50,828,940 gallons. Butter made amounted to 16,825,069 pounds. The number of chickens on the farms in 1924 was 16,408,080, valued at \$13,319,488.

Fisheries. In 1908 there were 934 persons engaged in fisheries, the capital invested was \$129,000, and the value of products, \$192,000. The products present a large variety, but lake herring, German carp, buffalo fish, and catfish are the principal species caught.

Forest Products. The production of rough lumber (in which Minnesota ranked twelfth among the States) in 1909 was 1,561,508,000 board feet. Production fell, for 1926, to 471,000,000 board feet. The production of lath was 224,500,000 in 1926 and that of shingles, 740,000. Of the total output of lumber, very nearly five-sixths formerly was white pine, Minnesota supplying slightly more than one-third of the total quantity of this variety of lumber produced in continental United States in 1909. The most important of the other varieties of lumber cut were spruce, tamarack, and hemlock. Minnesota was long the leading State in the production of lath, with 12.9 per cent of the total for the United States in 1909. In addition to the foregoing, there were produced on the farms in 1909 forest products valued at \$5,181,508.

Manufactures. Minnesota is of less importance as a manufacturing than as an agricultural State. Its large mineral output contributes little to its manufactures, as most of the products are shipped out of the State, but its extensive forests and large wheat fields furnish raw

material for the two most important industries. The value of manufactured products per capita in 1909 was \$197. In that year, Minnesota ranked thirteenth among the States in the gross value of products.

Minnesota was in 1909 the leading State in the Union in the value of products of flour-mills and gristmills, contributing 15.7 per cent of the total in 1909. Its importance in this industry is due to its large production of wheat, to its advantageous geographic location, particularly with respect to the adjoining grain-growing States, and to the excellent and modern facilities afforded for handling grain both by rail and by water. In both 1904 and 1909 Minnesota ranked first in the quantity and value of its wheat-flour products milled, third in respect to its barley and oat products, and fourth in respect to its rye products. In 1909 there were produced 22,712,534 barrels of white flour, or more than one-fifth of the total output of this cereal product in the United States. Second in value of products were the industries connected with the manufacture of lumber and timber. In addition to the logging plants, these included saw-mills, planing mills, and wooden packing-box factories. For further statistics in regard to this industry, see *Forest Products*, above. Pork was the most important product of the meat and slaughtering industry, while butter formed the chief output of the dairies. (See *Live Stock and Dairy Products*, above.) Radical changes in the methods of agriculture and the rotation of flax with other crops have made it more profitable to raise flax, thereby stimulating the manufacture of linseed oil. The growth of this industry has been remarkable, for while in 1899 there were only three establishments manufacturing this oil and its output was valued at only \$1,548,000, the output in 1909 was valued at \$11,037,000. In the manufacture of malt liquors, the State in 1909 held high rank. Other important industries were those engaged in the manufacture of belting and hose, leather, iron and steel, millinery and lace goods, pottery and fire-clay products, and steam packing.

The total number of wage earners in 1909 was 84,767, of whom 73,259 were males. For the great majority of wage earners, the usual hours of labor ranged from 54 to 60 a week, only 16.7 per cent of the total being employed in establishments where the hours were less than 54 and only 4.1 per cent in establishments where they exceeded 60 a week.

In 1909 the eight cities of over 10,000 population produced 64 per cent of the total value of manufactured products and had 66.9 per cent of the average number of wage earners. The most important manufacturing city is Minneapolis (q.v.), which had, in 1909, 26,962 wage earners and manufactured products valued at \$165,404,680. The most important industries of the city are those connected with the manufacture of flour. St. Paul (q.v.) is the second city in value of manufactures. There were here, in 1909, 19,339 wage earners, and the value of its manufactured products was \$58,990,025.

The progress of manufacturing in Minnesota since 1909 has been considerable, but much affected by the economic irregularities incident to the period. The value of the products of all the manufactories of the State was higher in 1914 than in 1909, being \$493,354,000 for 1914. In response both to advance in prices and to the war demand, the total of such products rose

farther and very sharply to \$1,218,130,000 for 1919. There followed the decrease in manufacturing value totals common to all States in the two years that ensued and for 1921 the total was \$843,805,000. Thereafter, the yearly total increased to \$956,720,000 for 1923 and, further, to \$1,090,087,515 for 1925. For 1927 the value of the manufacturing product was \$1,066,727,215. At this figure, it was considerably more than twice the total of 1914; allowing for the presumption that the commodity level of 1927 was higher by one-half than that of 1914, the total for 1927, in terms of 1914 values, was more than one-third above that of 1914. The industries connected with grain played less great a part in manufacture in 1925 than in 1909. In 1909 flour-mill and gristmill products, which amounted to \$139,136,000, formed about 27.5 per cent of the entire manufactures of the State as measured by value; in 1925 the production of the grain mills was of the value of \$215,637,578 and constituted but an approximate 20 per cent of the total of all manufactures of that year. The fact that the price levels of the grains had not entirely emerged from the depression that succeeded the war inflation was in part responsible for the 1925 showing, which was consequently not to be taken as accurately reflecting the magnitude of the 1925 output of the grain mills.

The number of wage earners employed in the manufactories of the State was but slightly greater in 1927 than in 1914. There were employed in 1914, 92,834 such wage earners; in 1927, 98,833. The highest recorded average of wage earners for any one intervening year had been that of 115,623 in 1919. The wage earners of 1927, however, received wages to the total of \$123,619,231, as against \$58,507,000 paid those of 1914. The wage total of 1927 was therefore more than twice that of 1914, while the average yearly wages of 1927 were about \$1220, as against some \$630 for 1914. The average wages thus were nearly double those of 1914, while the estimated cost of living in Minneapolis in 1927 was but 152 per cent of that of 1913, a year to which 1914 somewhat closely approximated. Increased manufacturing prosperity was thus indicated in an average remuneration to the worker about 30 per cent greater in absolute value in 1927 than in 1914. Of the entire value added to material by manufacture, the wage worker in Minnesota in 1927 obtained about 36 per cent; the total value added by manufacture being for that year \$340,336,471. The proportion was in line with that for the United States as a whole, the indication being that the wage element in manufacturing in Minnesota in 1927 was close to normal for American conditions at that time. It deserves note that the value added by manufacture in 1927 was less than one-half of the cost of raw materials, supplies, and fuel. This was a much lower proportion than that for the United States as a whole. It indicated that, in the case of Minnesota, the character of manufacturing tended to the less elaborate processes.

Besides the leading industry of grain milling, mentioned above, the industry of slaughtering and meat packing occupied an increasingly important place in the State. Its products of 1925 were valued at \$182,555,429. The most active manufacturing centre in 1925 continued to be Minneapolis, which in that year produced \$338,824,000 of goods. The manufacturing production of St. Paul in 1925 attained \$194,013,000. While the gross increase in the case of Min-

neapolis was greater from 1914 to 1925, the manufacturing production of St. Paul during the same period increased at a somewhat higher rate.

Transportation. The State has very favorable facilities for both water and rail transportation. St. Paul and Minneapolis form one of the most important centres for transcontinental railway traffic, while Duluth, at the west end of Lake Superior, has larger shipments by water than any other city on the Great Lakes and ranks as one of the important ports of the United States. Transportation on the Mississippi River was formerly very active, but has decreased on account of the development of the railroads. On the St. Lawrence system, however, it has greatly increased. The availability of lake transportation has been one of the greatest factors in the development of the mining industry. The southern and western parts of the State are well supplied with railroads. The total mileage of main line on Jan. 1, 1927, was 8790. The most important lines and their total mileages are the Great Northern, 2100; the Chicago, Milwaukee & St. Paul, 1230; the Northern Pacific, 1039; the Chicago & Northwestern, 650; the Chicago, St. Paul, Minneapolis & Omaha (Chicago & Northwestern), 431; the Chicago Great Western, 399; the Minneapolis & St. Louis, 378; the Duluth, Missabe & Northern, 303; the Duluth & Iron Range, 291; the Chicago, Rock Island & Pacific, 236; and the Chicago, Burlington & Quincy, 24. The State has a railroad and warehouse commission, which hears and passes judgment upon complaints. The efforts of this commission to regulate railroad rates on interstate railroads resulted in several important decisions in regard to railroad rates by the State courts and by the United States Supreme Court. For a discussion of these matters, see **RAILWAYS.**

Banks. The first banking law of Minnesota was passed in 1858, at the first session of the Legislature; the law was amended in 1878, placing the banks under the control of the Public Examiner, who is ex-officio superintendent of banks. The law was amended and made more stringent in 1881, 1889, and 1895. Banking business in the State was unprofitable at first and all the State banks organized in 1858-68 were discontinued. In 1878 there were 17 and in 1898, 161 banks in operation. Savings banks are regulated by the Law of 1879, which placed them under the jurisdiction of the Bank Commissioner. On Oct. 10, 1928, there were 281 National banks, with an aggregate capital of \$36,678,000; surplus, \$20,800,000; cash, \$9,275,000; loans, \$332,903,000; and deposits, \$598,864,000. There were under State supervision in June, 1927, 894 State banks, 18 trust companies, one stock and six mutual savings banks.

Government. The present constitution was adopted on Oct. 13, 1857, and succeeded the organic Act providing for a territorial form of government passed on March 3, 1849. Amendments to the constitution may be made by a majority of both Houses of the Legislature, becoming a part of the constitution when approved by a majority vote of the people. A convention to revise the constitution may be called whenever two-thirds of the members of each branch of the Legislature think it necessary and the proposition shall have been favorably voted upon by the electors.

Legislative.—The Legislature consists of the Senate and the House of Representatives, which meet biennially. No session must exceed 90 legislative days. The number of members who compose the Senate and the House of Representatives is prescribed by law, but the members of the Senate shall never exceed one member for every 5000 inhabitants, and in the House of Representatives one member for every 2000 inhabitants. The House of Representatives has the sole power of impeachment. Representatives hold office for two years and Senators for four years.

Executive.—The executive power consists of the Governor, Lieutenant Governor, Secretary of State, Auditor, Treasurer, and Attorney General. The term of the Governor and Lieutenant Governor is two years. Each must have attained the age of 25 years and have been a resident of the State for one year next preceding his election. The term of the Secretary of State, State Treasurer, and Attorney General is two years. The term of the State Auditor is four years. The Lieutenant Governor is ex-officio president of the Senate.

Judiciary.—The judicial powers are vested in a supreme court, district courts, courts of probate, justices of the peace, and such other courts, inferior to the supreme court, as the Legislature may from time to time establish by a two-thirds vote. The supreme court consists of one Chief Justice and four associate justices, elected for a term of six years, and two commissioners appointed by the court. The State is divided into judicial districts, which are composed of contiguous territory. In each district one or more judges, as the Legislature may prescribe, are elected for a term of six years. There is a probate court in each organized county, and its judge is elected for a term of two years. Justices of the peace are elected in each county for two years.

Suffrage and Elections.—Every person of the age of 21 years and upward who is a citizen of the United States and who has resided in the State six months next preceding any election is entitled to vote. This includes mixed and pure Indians who have adopted the customs and habits of civilization. Women have long voted for school officers and members of library boards, and even before woman suffrage could hold any office pertaining to the management of schools or libraries. General elections are held biennially, on the first Tuesday after the first Monday in November, dating from 1884. In accordance with the amended election laws of 1912, a State-wide primary is held on the Tuesday seven weeks preceding any election, for the selection of party and other candidates for all elective State offices and those of cities of the first and second class. There are nonpartisan primary ballots for the judiciary and other offices. Candidates for office are chosen at primary election by voters of the several political parties and not otherwise. Candidates are limited in the character of personal expenditures incurred in connection with their campaigns and the total of all expenses must not be above limits specified for the various offices. All campaign literature must bear the name of its author and the inducing of persons to become or not to become candidates for office is prohibited. Wagering on elections is a violation of the law. Candidates must make itemized statement of all disbursements. Corporations are prohibited from mak-

ing political contributions. The Legislature of 1911 passed an Act providing for the direct nomination of United States Senators. By a law passed in 1912, Minneapolis, St. Paul, and Duluth are required to have nonpartisan primaries for municipal officers. The Legislature of 1913 enacted a measure providing for presidential primaries and the nonpartisan primary was extended to members of the Legislature.

Local and Municipal Government.—The Legislature may from time to time establish and organize new counties; but no new county shall contain less than 400 square miles, nor shall any county be reduced below that amount. The Legislature may organize any city into a separate county, when it has attained a population of 20,000 inhabitants, without reference to geographical extent, when a majority of the electors of the county in which such city is situated shall be in favor of a separate organization. Cities and towns have the power to adopt a home-rule charter. Cities of the first class with home-rule charters may regulate the sale of liquor in hotels.

Miscellaneous, Constitutional, and Statutory Provisions.—No corporation may be formed under special acts except for municipal purposes. Married women retain the same legal existence and personality as before marriage, may sue or be sued, and receive equal protection of all individual rights. Combinations to monopolize the markets for food products, or restrict the freedom of such markets, are criminal conspiracies. A constitutional amendment of 1926 permits the final or crop tax on forests. There are restrictions in the character of employment of children. The maximum hours of employment for children are 8 per day and 48 per week; for women, 10 hours per day and 58 per week for certain occupations and 9 hours per day and 54 per week for others. County boards are authorized to appropriate money to prevent the spread of tuberculosis. Five-sixths of a jury may return a verdict in civil cases after 12 hours' deliberation. There is a "blue sky" law relating to insurance companies. The Legislature of 1913 passed a workmen's-compensation act and created a minimum-wage commission to regulate the wages of women and minors. The Legislature of 1913 also enacted a measure providing for mothers' pensions in the State.

Finance. By the constitution of 1857, the State was prohibited from incurring debts for public improvements above \$250,000. An amendment adopted in 1858, however, permitted the issuing of \$5,000,000 of 7 per cent bonds to lend to the railroads under guaranty of first-mortgage bonds. Less than half of these bonds were sold, the railroads defaulted the interest on their mortgage bonds, and the State acquired their property by foreclosure. The State was unable to meet the interest payment, and in 1860 the debt on these bonds was repudiated. In 1861 the obligations were resumed, when the old bonds were exchanged for new ones at the rate of 50 per cent. This gave the State a debt of \$4,253,000, which was gradually reduced. In 1912 it amounted to \$900,000. Later came an era of debt expansion marked by the issue of soldiers'-bonus bonds (1920), rural credit bonds (1923-24) and county highway bonds for which the State was regarded as responsible. Public trust funds in 1926 amounted to \$107,944,653; sinking fund assets, to \$40,851,388. The per-capita debt

in that year was \$20.91. The total receipts from all sources for the fiscal year ending June 30, 1926, amounted to \$92,306,611. The disbursements for the same period amounted to \$78,376,515. There was a balance at the beginning of the year of \$14,445,363 and at the end of the year, of \$13,930,096. The chief sources of revenue are railroad taxes, general taxes, motor vehicle and fuel taxation, and permanent trust funds.

Militia. In 1920 the males of militia age, between 18 and 44 years, numbered 526,532. The organized militia consists of three regiments of infantry and one of field artillery. There were, in 1928, 343 officers and 4000 enlisted men. There is a State Naval Militia organization with headquarters at Duluth. Its personnel consisted in 1927 of 26 officers and 298 enlisted men and it maintained the receiving ship, *Essex*, and the United States gunboat, *Paducah*, stationed on Lake Superior.

Population. In 1920 Minnesota ranked seventeenth in population among the States. The population by decades since its organization as a Territory is as follows: 1850, 6077; 1860, 172,023; 1870, 439,706; 1880, 780,773; 1890, 1,310,285; 1900, 1,751,304; 1910, 2,075,708; 1920, 2,367,125. The estimated population on July 1, 1928, was 2,722,000. In 1920, the population per square mile was 29.5. The urban population in places of 2500 or over was 1,051,593 in 1920. The native white population numbered 1,862,772; the foreign-born white, 486,164; and the negro, 8809. There were also 8761 of Indian parentage. Of the foreign-born whites, those of Swedish, German, and Norwegian origin predominated, in the order named. These three nationalities contributed about 62 per cent of the total foreign-born population, which was about equally divided among them. By sex, the population was divided into 1,245,537 males and 1,141,588 females. Persons of voting age numbered 1,380,834.

There were but 11 cities in 1920 that had populations of 10,000 or over. The principal cities of the State, with their populations in 1910 and in 1920, are Minneapolis, 301,480 and 380,582; St Paul, 214,744 and 234,698; Duluth, 78,466 and 98,917; St. Cloud, 10,600 and 15,873; Virginia, 10,473 and 14,022; Mankato, 10,365 and 12,469; Stillwater, 10,108 and 7735; Winona, 18,583 and 19,143.

Education. The high standards of education in Minnesota are reflected in the relatively small portion of illiterates. In 1920 there were 34,487 persons of 10 years of age or more who were illiterate, a proportion of 1.8 per cent of the entire population. Among the whites of native birth, the percentage was four-tenths of 1 per cent and among foreign-born whites 5.4 per cent. The school population, ages 5 to 17 years, in 1926 was estimated as 651,623; of this number, 549,899 were enrolled in the public schools. According to the report of the State Superintendent of Education, the total enrollment in public schools in 1914 was 457,041. The total number of teachers in 1926 was 21,958, of whom 16,668 were engaged in elementary instruction and 5290 were in secondary schools. The average yearly salary of all teachers in the public schools of the State in 1926 was \$1215. The total current expenditure for public schools in the year 1925-26 was \$42,494,825.

The State of Minnesota gives special aid to schools which maintain training and agricultural departments and to high and graded

schools, consolidated schools, and rural schools. There were, in 1914, 26 vocational training schools, in which were enrolled 2927 pupils. The Legislature of 1913 enacted a law which requires definite training of all persons who enter upon teaching in the public schools.

The Legislature of 1911 enacted a compulsory-education law which is unusually comprehensive. The same Legislature passed a law regulating prices of textbooks, which, on the vote of the district or of the school board, may be supplied free or sold at cost.

Normal schools are maintained at Winona, Mankato, St. Cloud, Moorhead, and Duluth. The total enrollment in State normal schools in 1926 was 4532. The University of Minnesota, which is part of the educational system of the State, is at Minneapolis. Other institutions of collegiate rank are Carleton College and St. Olaf College at Northfield, Hamline University at St. Paul, Macalester College at St. Paul, and Gustavus Adolphus College at St. Peter. All these are coeducational. Albert Lea College at Albert Lea is the only women's college. St. John's University (Roman Catholic), at Collegeville, and Augsburg Seminary, at Minneapolis, are colleges for men only.

Charities and Corrections. The charitable and correctional institutions are in the hands of the State Board of Control, created in 1901. It consists of three members appointed by the Governor and Senate for the term of six years, and has full power to manage and control the State charitable and penal institutions, with authority in financial matters in certain State schools, including those for the deaf and blind. Besides controlling the 18 institutions for the various classes of defectives, sick, and delinquents, it supervised certain of the country institutions and operated a number of prison industries, appointed county child welfare boards, exercised legal guardianship over committed children, and established the paternity of illegitimates.

The various State institutions, with the numbers of their inmates on June 30, 1928, were: Asylums and mental hospitals at Anooka, 1029; Hastings, 992; Willmar, 689; Fergus Falls, 1699; Rochester, 1459; St. Peter Hospital, 1524; Asylum for Dangerous Insane, 152; School for Feeble-Minded, 1979; Home School for Girls, 200; Colony for Epileptics, 167; State Training School, 328; Reformatory, 843; Reformatory for Women, 77; State Prison, 1228; Hospital for Inebriates, 14; School for the Blind, 88; School for the Deaf, 270; State Public School, 417; Sanatorium for Consumptives, 216; Hospital for Crippled Children, 250. The manufacture of twine and farm machinery has been carried on successfully in the prison. The State hospital for the care of inebriates and persons addicted to the drug habit was opened in December, 1912. The Legislature in 1911 provided for the indeterminate sentence of prisoners convicted of any crime except treason and murder, and for a State board of parole. Life imprisonment was substituted for death as a punishment for murder in the first degree.

Religion. The noteworthy characteristic of the religious situation in Minnesota is the great predominance of the Roman Catholic and the Lutheran churches. The strongest of the other denominations represented are the Methodists, Baptists, Presbyterians, Congregationalists, and Protestant Episcopalians.

History. Radiason and Groseilliers, Frenchmen, visited, probably in 1660, what is now Minnesota. About 1678 Daniel Du Luth built a fort at the mouth of the Pigeon River, on the north shore of Lake Superior. In 1680 the Falls of St. Anthony were discovered by Louis Hennepin, a Franciscan priest. Before 1700 there were trading posts on Lake Pepin and on the Minnesota River. A part of Minnesota was included in the extensive territory ceded by France to Great Britain in 1763. In 1766 it was explored by Capt. Jonathan Carver, of Connecticut. In 1783 it became a possession of the United States. The part of the State east of the Mississippi belonged at different periods to the Territories of Indiana, Michigan, and Wisconsin, Northwest Territory, and Illinois Territory. The region west formed part of the Territories of Missouri (earlier District of Louisiana), Michigan, Wisconsin, and Iowa. The government in 1805 bargained with the Indians for land at the mouths of the St. Croix and Minnesota rivers as sites for military posts. The exploring expedition of Lieutenant Pike in 1805 was followed by many others within the succeeding 40 years; and with an increased knowledge of the country came the first important beginning of immigration. Fort St. Anthony (Snelling) was built in 1819-21; in 1822 a clearing was made at the Falls of St. Anthony and a mill was built, and in 1823 the first steamboat ascended to the falls. The next settlements made were by a colony of Swiss, near Fort Snelling in 1827 and at Stillwater in 1843. Two years before the latter date, Father Galtier had erected a log chapel a little southeast of the Falls of St. Anthony and dedicated it to St. Paul. This was the nucleus of the present city of that name. The Indian titles to the lands east of the Mississippi were not extinguished until the year 1838, and it was not until March 3, 1849, that the Territory of Minnesota was organized, with the Missouri River as its west boundary. In 1851 the Indian titles to the lands (except reservations) between the Mississippi and the Red River of the North were extinguished and immigration increased rapidly. On May 11, 1858, Minnesota was admitted as a State. The educational institutions for which the State is noted took their rise early in the history of the Territory. Hamline University, at St. Paul, was founded in 1854, and St. John's University, at Collegeville, was established three years later. In 1862 the Sioux Indians, under Little Crow, dissatisfied with the settlers' treatment of them, attacked and destroyed many of the frontier settlements. Over 500 white settlers and soldiers were killed and 25,000 people were driven from their homes. The Indians were decisively defeated at Wood Lake on Sept. 22, 1862, and after engaging in sporadic raids in 1863 were removed west of the Missouri. In spite of the horrors of Indian war, immigration continued undiminished; it was stimulated by the activity of immigration agents in the Eastern States and in Europe and was encouraged by the enactment of liberal homestead laws. From the sale of its extensive public lands, the State obtained a very large school fund, which it employed in building up an admirable school system.

Minnesota was consistently Republican in State politics from 1860 to 1898, when the Democrats, Populists, and Silver Republicans defeated the Republicans and elected their candidate for Governor. The Republicans regained power in 1901 and held it until 1905, when the

personal popularity of the Democratic candidate, John A. Johnson, secured his election. The Republicans, however, controlled the other State offices. Governor Johnson was reelected for three successive terms. In 1908 he had become so prominent a national figure that he was one of the leading candidates for the Democratic presidential nomination and the delegates from Minnesota were instructed to vote for him in the National Convention.

In the presidential election of 1908, Taft carried the State with 155,416 votes, compared with 109,504 for Bryan. Governor Johnson was reelected, but died on Sept. 20, 1909, and was thereupon succeeded by Lieutenant Governor Eberhart, a Republican. Governor Eberhart was elected in 1910. A new primary law providing for the nomination of State officers and delegates for the National Convention went into effect in 1912. The Progressive party developed great strength in that year. Roosevelt easily carried the State. In 1914 the Democrats regained power, electing W. S. Hammond Governor. At the decline of the Progressive movement, the dissatisfied farm element directed its support, first to the Non-Partisan League and later to the Farmer-Labor party, which elected two United States Senators. Thomas D. Schall, Republican, was elected Senator in 1924.

The following is a list of Governors of Minnesota since its organization as a territory:

TERRITORIAL

Alexander Ramsey	1848-53
Willis A. Gorman	1853-57
Samuel Medary	1857-58

STATE

Henry H. Sibley Democrat	1858-60
Alexander Ramsey Republican	1860-64
Stephen Miller	1864-66
William R. Marshall	1866-70
Horace Austin	1870-74
Cushman K. Davis	1874-78
John S. Pillsbury	1878-82
Lucius F. Hubbard	1882-87
Andrew E. McGill	1887-89
William B. Merriam	1889-91
Knute Nelson	1891-95
David M. Cough	1895-99
John Lind	1899-1901
Samuel R. Van Sant	1901-05
John A. Johnson	1905-09
Adolph O. Eberhart	1909-15
William S. Hammond	1915-17
Joseph A. A. Burnquist	1917-21
J. A. O. Preus	1921-25
Theodore Christianson	1925-

MINNESOTA, UNIVERSITY OF. A coeducational State institution of higher learning in Minneapolis, Minn., established by an Act of the Territorial Legislature in 1851 and confirmed by the State constitution adopted in 1857. The present charter was adopted in 1868 and the first collegiate work was begun in the following

year. Its government is vested, since the death in 1901 of the life regent, John S. Pillsbury, in a board of 12 regents, nine appointed by the Governor of the State and holding office for six years, and three ex-officio members—the Governor, the State Superintendent of Public Instruction, and the president of the university. The university comprises the following colleges, schools, and departments: 1. The Graduate School, with advanced courses in all branches. 2. The College of Science, Literature, and the Arts, offering four-year courses, largely elective, leading to the degree of bachelor of arts, courses in which the senior work is offered conjointly with the Schools of Law, Medicine, Dentistry, and Chemistry, leading to the same degree; a four-year course in arts and music, leading to the degree of bachelor of arts and music; also a four-year course in science and medicine, leading to the degree of bachelor of science. 3. The College of Engineering and the Mechanic Arts, offering five-year courses in civil, mechanical, electrical, and architectural engineering and architecture, leading to the degrees of civil, mechanical, electrical, and architectural engineer and architect. The degrees of bachelor of science in engineering and in architecture are conferred at the end of the fourth year. 4. The Department of Agriculture, embracing (a) the Colleges of Agriculture and Forestry, offering four-year courses, leading to the degrees of bachelor of science in agriculture, in home economics, and in forestry; (b) the Schools of Agriculture, offering three-year courses adapted especially to the needs and opportunities of farm boys and girls; (c) short courses in dairying, farm management, and traction engineering; (d) the experiment stations, offering research advantages; (e) extension work in agriculture. 5. The Law School, giving a three-year course, leading to the degree of bachelor of laws. 6. The Medical School, with a five-year course, including one year of hospital internship, leading to the degree of doctor of medicine. 7. The College of Dentistry, with a three-year course, leading to the degree of doctor of dental surgery. 8. The College of Pharmacy, offering a two and a three year course, leading to the degrees of graduate in pharmacy and pharmaceutical chemist respectively. 9. The School of Mines, offering three five-year courses, leading to the degrees of engineer of mines, engineer of mines in geology, and metallurgical engineer. 10. The School of Analytical and Applied Chemistry, with two five-year courses, the Applied Course leading to the degree of chemical engineer, the other, offered conjointly with the College of Science, Literature, and the Arts, leading to the degrees of bachelor of arts and bachelor of science in chemistry; and a four-year course in analytical chemistry, leading to the degree of bachelor of science in chemistry. 11. The College of Education for the training of teachers and supervisors, with a two-year course, leading to the degree of bachelor of arts in education. 12. The University Extension Service, offering educational opportunities to the people of the State through (a) correspondence courses, (b) evening classes, (c) lecture courses, (d) field debates on public questions, (e) a reference bureau. The university also has charge of the geological and natural history survey. The degrees conferred for graduate work are the master's degree in arts, science, and pharmacy, and the doctor's degree in philosophy and medicine. No honor-

ary degrees are conferred. The departments of law, medicine, and education require two years of collegiate preparation. In all other departments students are admitted on examination or on certificate from accredited schools of the State. Tuition ranges from \$30 to \$150 a year. In 1913-14 the faculty numbered 608 and the attendance was 8992, of whom 3529 were women. Of this number 4155 were of college grade, 3209 subcollegiate, and 1628 extension. The general library contained 175,000 volumes, and there were special libraries in connection with the various departments of instruction. The laboratories are extensive and well equipped. There is an herbarium with 400,000 specimens. There are dormitories for the School of Agriculture, and one dormitory accommodating 90 women on the main campus. The main university grounds comprise about 109 acres, valued at \$2,000,000. The 32 buildings are valued at \$3,463,000, and their equipment at about \$1,805,000. The State experimental farm, located between Minneapolis and St. Paul, consists of about 420 acres, and is valued at \$413,000. The buildings and equipment of the Department of Agriculture are estimated at \$1,480,000. The university is supported by the income of its permanent endowment, a State tax of $\frac{3}{8}$ mill, and special legislative appropriations for support, buildings, and equipment. The gross income for 1913-14, exclusive of special appropriations, was \$2,445,491. The endowment was \$1,605,356.82, and the value of all the university property, \$12,112,000. George Edgar Vincent has been president since April, 1911. Consult E. E. Slosson, *Great American Universities* (New York, 1910).

MINNESOTA RIVER. An affluent of the upper Mississippi (Map: Minnesota, D 6). It rises on the east slope of the Dakota foothills (Coteau des Prairies) in the northeastern part of Marshall Co., S. Dak., at an elevation of about 1896 feet above sea level. It flows southeastward to the State line, where it enters Bigstone Lake, which is 26 miles long, from 1 to 1½ miles wide, and shallow. This upper reach of the river often runs dry. The river leaves the lake at Ortonville and flows southeast to Mankato (225 miles), where it turns abruptly and thereafter flows northeast to its junction with the Mississippi, a few miles below the Falls of St. Anthony and between the cities of Minneapolis and St. Paul. Its total length is about 470 miles, and its drainage basin of 16,600 square miles extends nearly across the southern part of the State. It is by far the largest confluent of the Mississippi in Minnesota. Its chief tributaries are Pomme de Terre and Chippewa rivers from the north, and Lac qui Parle, Redwood, Cottonwood, and Blue Earth rivers from the south. It is navigable for steamers 45 miles, and at high water small vessels can ascend it 295 miles, beyond which it is obstructed by falls and rapids.

MINNEWAUKON, min'né-wá'kón, LAKE. The largest lake in North Dakota, more frequently known as DEVIL'S LAKE (Map: North Dakota, G 1). It is situated in the northeastern part of the State and is 40 miles long and from 2 to 12 miles broad.

MINNEWIT, PETER. See MINUIT, PETER.

MINNOW (ME. *menow*, from AS. *myne*, minnow, probably from AS. *min*, Icel. *minnr*, Goth. *minniza*, OHG. *minniro*, Ger. *minder*, Lat. *minor*, less, Gk. *μῦνθηρ*, *minynthein*, to lessen, Skt. *mī*, to diminish). The name popularly ap-

plied to almost any small fish. More technically it applies to members of the family Cyprinidae, which includes the roach, dace, carp, etc.; specifically, in England, *Leuciscus phoxinus*. This is a small fish about 3 inches long, abundant in gravelly bottomed streams. It is, of course, unimportant as food except for larger fishes. In the United States the name usually belongs to various small cyprinodonts, mainly of the large genus *Notropis*, living in the lesser streams and frequently called shiners. The largest and best known of these is the golden shiner (*Notropis hudsonius*), which has a very small head, but is sometimes a foot in length. (See DACE.) These fishes are mostly bottom feeders, are oviparous, carnivorous, and devour much spawn of their own and other kinds of fishes. The top minnows are of a different group, being killifishes (q.v.) of the genus *Gambusia*, and take their name from their surface-feeding habits. Along the eastern and southern coasts the common minnow of brackish water is the mummichog (q.v.). Consult D. S. Jordan, *Fishes* (New York, 1908), and id., *Manual of the Vertebrates of the Northern United States* (11th ed., rev. and enlarged, Chicago, 1914). See PLATES OF CARPS AND THEIR EUROPEAN ALLIES; DACE AND MINNOWS; KILLIFISHES AND TOP MINNOWS.

MINO, or in Portuguese **MINHO**, mé'nyô (Lat. *Minius*). The principal river of Galicia, in northwest Spain (Map: Spain, B 1). It rises in the mountains of the Province of Lugo and flows in a southerly and southwesterly direction, forming a part of the boundary between Spain and Portugal, until it enters the Atlantic through a wide estuary. Its total length is 211 miles, for the last 25 of which it is navigable for small vessels, but it is much obstructed by reefs, islands, and shifting sand banks. Its banks are very fertile, and salmon and lamprey abound, yielding a considerable industry.

MINO'AN CIVILIZATION. See ARCHAEOLOGY, II, *Minoan*, or *Egean*, *Period*; CNOSSUS; CRETE; EVANS, SIR ARTHUR; GOURNIA.

MINO DA FIOSOLE, mé'nô dá fyá'zô-lá (1431-84). A Florentine sculptor of the early Renaissance. He was born at Poppi in the Casentino valley. While employed as a stonemason at Florence he became the friend and pupil of Desiderio da Settignano. His home was at Florence, but there is documentary evidence to show that he was employed at Rome in 1454, 1463, and 1464. In 1473 he was working upon the monument to Pope Paul II, of which there are fragments in the Grotte Vaticane, under St. Peter's Church, and from 1475 to 1480 he executed various commissions under Sixtus IV. He died at Florence, July 11, 1484. His work possesses great charm and delicate finish, but is lacking in originality. Its high reputation is due to rich decoration and to a certain naïveté of expression, especially in his numerous portrait busts, which were executed under the influence of Desiderio da Settignano and are his best work. Besides these his chief works are monuments, altars, and tabernacles in the churches of Florence, Fiesole, and Rome. His most important achievements in Florence are in the church of La Badia: the monuments of Bernardo Giugni (1466) and the Margrave Hugo of Tuscany (1481). There are several tabernacles by him in Santa Croce, and in the Museo Nazionale are busts of Piero de' Medici (1453), Giuliano de' Medici, and Rinaldo della Luna (1461). One of his best works, if not his most

important, belongs to his early period: the monument of Leonardo Salutate, Bishop of Fiesole (died 1466), in the cathedral of that city; it is surmounted by a fine bust. The altar in the cathedral, which is also by Mino, shows plainly the limitations of his art. A beautiful piece of Renaissance decoration is the tabernacle at Santa Maria in Trastevere, Rome, in which city are also his monument of Cardinal Forteguerri in Santa Cecilia and the monument of Francesco Tornabuoni in Santa Maria sopra Minerva, his latest Roman work and one of his happiest inspirations. His other works include busts of Niccolò Strozzi, in the Museum of Berlin, which also possesses his only female bust, that of a young girl, and San Giovannino, in the Louvre; and reliefs, including numerous Madonnas, from his altars and monuments, to be found in many museums and private collections. Consult: Semper and Barth, *Hervorragende Bildhauer-Architekten der Renaissance* (Dresden, 1880); C. C. Perkins, *Handbook of Italian Sculpture* (New York, 1883); Wilhelm Bode, *Denkmäler der Renaissance Skulptur Toscana* (Munich, 1892-1905); Angeli, *Mino da Fiesole* (Florence, 1905).

MINOR (Lat., less). A term in music applied to intervals and modes. (1) The interval between any note and another is named according to the number of degrees between them on the scale, both notes included. The interval between C and E is called a third; that between E and G is also a third; but these intervals are unequal, the one consisting of four semitones, the other of three; the former is therefore distinguished as a major, the latter as a minor interval. (2) There are two modes in which a musical passage may be composed. Whereas the major mode makes use of but one form of scale, which is the same whether *ascending* or *descending*, the minor mode recognizes two forms of scale, the *harmonic* and *melodic*. Modern music conceives a mode as a system of three fundamental chords, which contain all the tones proper to the scale of that mode. These chords are the tonic, dominant, and subdominant. Arranging the tones of the *pure* minor scale as elements of these three chords we have the following:

where all three chords present themselves as *minor* (because having the *minor* third), just as the corresponding chords are *major* in the *major* mode. (See MAJOR.) Arranging these tones in this diatonic order as a *descending* scale, beginning with the highest tone of the tonic chord (e), the following results: e, d, c, b, a, g, f, e. Here we have a *pure* minor scale which is identical with the Dorian mode of the Greeks. (See GREEK MUSIC.) Comparing this *descending* minor with the *ascending* major scale, we find each to be the exact opposite of the other, thus establishing the polarity of major and minor already known to Zarlino and Tartini, but fully developed only in 1853 by Hauptmann. Where the *ascending* major has the major third (on third degree) and semisteps (3-4, 7-8) the *descending* minor has the *same* in the *same* place:

c, d, e, f, g, a, b, c.
e, d, c, b, a, g, f, e.

For practical composition, however, the scale always begins with the tonic. In the progression a, b, c, d, e, f, g, a, the whole step from 7 to 8 was found unsatisfactory to the ear, which imperatively demanded a semistep. By raising g a semistep this leading tone was obtained, but the step from 8 to 7 was augmented. It was only during the nineteenth century that this form of the minor scale a, b, c, d, e, f, g \sharp , a, which is known as the *harmonic* minor scale, was proclaimed as the *normal* form. Before that theorists had been afraid of the augmented second from 6 to 7 (a dissonance) and had overcome the difficulty by also raising the sixth degree a semitone, so that *ascending* the minor scale had this form: a, b, c, d, e, f \sharp , g \sharp , a, while *descending* the 7th and 6th degrees were restored to their original pitch. Thus, what is known as the *melodic* minor scale has two forms, one when ascending, the other when descending. Now, considering the *harmonic* form as the normal minor scale, modern musical theory establishes the dominant chord of both the major and minor modes as a *major* triad. Thus, the three fundamental chords of the modern minor mode present themselves as two minor triads (tonic and subdominant) and one major triad (dominant). See INTERVAL; MODES.

MINOR. In law, a person who has not attained the age of full legal capacity or the age of legal capacity with respect to the performance of certain acts. The term "minor" belongs strictly to the civil law, in which a person of full legal capacity is called major; but generally the term "minor" is used in English as synonymous with infant, under which title the statement of the general law of the subject will be found. In Scots law, minor is sometimes specifically used of an infant above the age of a pupil (12 years for females, 14 for males) and under the full age (21 years) of majority. See INFANT; PARENT AND CHILD.

MINOR, mé'nör, JAKOB (1855-1912). An Austrian scholar in Teutonic philology and literature, born at Vienna. He studied at the universities of Vienna (1874-78) and Berlin (1878-79), became a lecturer at the former (under Scherer, 1880), in 1882-84 held a chair in the Accademia Scientifico-letteraria of Milan, and in 1884-85 was professor of the German language and literature in the University of Prague. In 1885 he was appointed professor of Germanic philology at Vienna. His numerous publications include many editions of texts, such as volumes 73 (*Fabeldichter, Satiriker, und Popularphilosophen des achtzehnten Jahrhunderts*), 145 (*Tieck und Wackenroder*), and 151 (*Das Schicksalsdrama*), with introductory essays and annotations, in the "Deutsche National-Litteratur" series, and the Archduke Ferdinand's *Speculum Vitæ Humanæ* (1889); *Neuhochdeutsche Metrik* (1893), a valuable manual of German prosody, based on lectures given at Vienna in 1882; and important works in literary history and criticism, such as *Die Schicksalstragödie in ihren Hauptvertretern* (1883), *Goethes Faust (I. Teil, Entstehungsgeschichte und Erklärung* (2 vols., 1901); and an uncompleted study of Schiller, *Schiller, sein Leben und seine Werke*, vols. i and ii (1890), ranked, so far as it extends, among the best on the subject. He also edited the works of A. W. and F. Schlegel, A. von Arnim, C. Brentano, L. Tieck, and others.

MINOR, LUCIAN (1802-58). An American lawyer and author, born in Louisa Co., Va. He

graduated at William and Mary College in 1823 and five years later became Commonwealth attorney for his native county, an office which he held until 1852. In 1855 he was appointed professor of law in William and Mary. He wrote a part of John A. G. Davis's *Guide to Justices* (1838) and contributed the notes to Daniel Call's *Virginia Reports*. A tract of his, *Reasons for Abolishing the Liquor Traffic*, had a large sale, and after his death his *Travels in New England* were edited by James Russell Lowell for publication in the *Atlantic*.

MINOR, ROBERT CRANNELL (1840-1904). An American landscape painter, born in New York City. He studied under Diaz at Barbizon, France, and under Van Luppen and Boulanger in Antwerp, and traveled in Germany and Italy. He was elected to the Society of American Artists and the National Academy of Design. He exhibited not only in the United States, but at the Royal Academy, London, and at the salons of Paris and Antwerp. His choice of motives was restricted. He preferred subdued yet richly colored light effects, particularly the glow of sunset and the mystery of twilight, and followed Diaz in his massing of light and shade. His paintings include "Dawn," "Sundown," "The Stream," "October Days," "The Vale of Kennet," "Edge of the Wood," "Interior of the Forest," "Morning in June," "Sunrise on Lake Champlain," "Cradle of the Hudson," "Cloudy Moonlight."

MINOR BARONS. The term applied in the twelfth and thirteenth centuries in England to those tenants in chief of the King who did not receive a special summons to council and to military service, but were summoned by a general proclamation of the sheriff given in the county courts. The term was not used in England after the thirteenth century.

MINOR/CA (Sp. *Menorca*). The second largest of the Balearic Islands (q.v.). It is the easternmost of the group and lies 20 miles northeast of Majorca (Map: Spain, G 3). Area, 264 (with adjacent islets, 293) square miles. Its north half consists of rather low, rolling hills, generally arid and covered with heath; the south half is an undulating plateau cut by deep, fertile valleys. There are numerous bays on the northeast coast, in one of which is the harbor of Port Mahón (q.v.), the principal town. This harbor is one of the best in the entire Mediterranean. Though minerals are found on the island, agriculture is the chief occupation, the principal products being wine, oil, grain, flax, and sweet potatoes. Pop., 1900, 37,512; 1910, 41,939. Minorca was taken by the British in 1708 and held by them, with several intermissions, until 1802, when it was finally secured to Spain by the Treaty of Amiens. Consult: Sir C. R. Markham, *Story of Majorca and Minorca* (London, 1908); J. E. C. Flitch, *Mediterranean Moods: Footnotes of Travel in the Islands of Mallorca, Menorca, Ibiza, and Sardinia* (New York, 1911); H. W. Richmond, *Papers Relating to the Loss of Minorca in 1756* (London, 1913).

MINORCA. A class of domestic fowls resembling leghorns, but of more length of body and heavier mold. Their flesh is good for table purposes, but their chief value is as egg layers, in which they excel, producing very large white eggs. They are hardy, active in hunting for their food, and generally commendable. A Minorca cock should weigh eight pounds; a hen

six and a half pounds. This breed should be long-bodied and stand high upon strong, slate-black legs; the comb is larger than that of the leghorn; the wattles thin and pendulous; and the ear lobes pure white. Two varieties are recognized—the black and the white. In each case the color must be absolutely pure; the comb, face, and wattles bright red; eyes dark hazel or red. See Colored Plate of FOWLS, under POULTRY.

MINORIES, mi'nó-ríz, THE. A London parish and street leading northward from the Tower to Aldgate, now forming with Houndsditch the Jewish quarter of the city. The name is derived from the nuns of St. Clare, called Sorores Minores, or Minoreseae. The church of the Trinity, once belonging to a nunnery of the order, still exists in the Minorities.

MINORITES. See FRANCISCANS.

MINORITY REPRESENTATION. See CUMULATIVE VOTING; REPRESENTATION.

MINOR PROPHETS. A common designation for a group of 12 prophetic books in the Hebrew canon, which in the English Bible form the close of the Old Testament. It was employed as early as the time of Augustine and Rufinus, who are careful to explain that its use is occasioned by the brevity of the books and does not characterize their merit or importance. The corresponding designation, major prophets, is applied to the longer books of Isaiah, Jeremiah, Ezekiel, and Daniel. The Hebrews called this group of writings the Twelve, and this nomenclature was followed by the Greeks. (See BIBLE.) The first reference to the collection is in Ecclesi. xlix, 10, a section probably written in the time of John Hyrcanus. The books included in the collection, in the order in which they are arranged in the Hebrew Bible, are Hosea, Joel, Amos, Obadiah, Jonah, Micah, Nahum, Habakkuk, Zephaniah, Haggai, Zechariah, Malachi. This order is retained in the English Bible. In the Greek version the arrangement is as follows: Hosea, Amos, Micah, Joel, Obadiah, Jonah, Nahum, Habakkuk, Zephaniah, Haggai, Zechariah, Malachi. Both arrangements no doubt were intended to be chronological. There is a general advance from the Assyrian to the Chaldean and Persian periods. The three prophets of the Chaldean period (Nahum, Habakkuk, Zephaniah) and the three of the Persian period (Haggai, Zechariah, Malachi) are given in the same order. On the other hand the earlier prophets seem to have formed two groups in the Greek, viz., Hosea, Amos, Micah, and Joel, Obadiah, Jonah. It is significant that of these six only the first group of three can be assigned to the Assyrian period in the light of modern criticism. It would appear, therefore, that the late books, Joel, Obadiah, and Jonah, once were appended to the others, but subsequently were copied after the prophets of the Assyrian period on account of the reference to Jonah in 2 Kings xiv. 25. The same consideration may have led to the placing of Jonah before Micah as in the Hebrew recension. For the dates of the books and further information, consult the articles upon the individual books.

Bibliography. Many commentaries have been written upon the 12 minor prophets as a whole. The following are the more recent: Rosenmüller, *Prophete Minores* (2d ed., Leipzig, 1827); E. B. Pusey, *The Minor Prophets* (2 vols., London, 1860); E. Henderson, *Commentary on the Twelve Minor Prophets* (ib., 1860-61); G. H. A.

von Ewald, *Propheten des alten Bundes* (2d ed., Göttingen, 1867); Reuss, *La Bible*, vol. ii (Paris, 1876); Ferdinand Hitzig, *Die zwölf kleinen Propheten* (4th ed., Leipzig, 1881); Knabenbauer, *Commentarius in Prophetas Minores* (Paris, 1886); F. W. Farrar, *The Minor Prophets*, in "Men of the Bible Series" (London, 1890); Deane, *Minor Prophets* (ib., 1893); Robertson Smith, *Prophets of Israel* (2d ed., 2 vols., ib., 1895); Nowack, *Die kleinen Propheten* (Göttingen, 1897); Julius Wellhausen, *Die kleinen Propheten* (3d ed., Berlin, 1898); Marti, *Dodeka-propheton* (Tübingen, 1904); Horton-Driver, in *Century Bible* (London, 1906); Hoonacker, *Les douze petits prophètes* (Brussels, 1908); H. K. von Orelli, *Kleine Propheten* (3d ed., Munich, 1908; Eng. trans. of 1st ed., New York, 1893); G. A. Smith, *Book of the Twelve Prophets* (new ed., 2 vols., New York, 1912).

MINOS (Gk. *Minos*). According to Greek story, a king of Crete, son of Zeus and Europa, brother of Rhadamanthus and Sarpedon, and father of Ariadne, Deucalion, and Phædra. In the ordinary version he appears as a just and wise ruler, governing Crete and the adjacent islands three generations before the Trojan War and giving them a code of laws received from his father, Zeus. He was a powerful monarch, establishing the first fleet and clearing the Ægean of pirates. He thus exercised a sway over the Greek coast lands. After his death his reputation for justice led the gods to make him a judge in the lower world, where with Rhadamanthus and Æacus he passed sentence on the souls of the dead. In contradiction to this character is the group of legends which gather about the Minotaur, where he appears as at first depriving Poseidon of his due offering, the bull sent by the god from the sea in answer to his prayer. From this bull and Pasiphaë, wife of Minos, sprang the Minotaur (q.v.), for whose keeping Dædalus (q.v.) built for Minos the Labyrinth (q.v.). When his son Androgeus was slain by the Athenians, Minos made war upon them and compelled them to pay the tribute of seven youths and seven maidens to be food for the Minotaur, until Theseus (q.v.) released them by killing the monster. The cruel character of Minos in this legend led later writers to distinguish two kings, the elder, a son of Zeus, who was just, and his grandson, who was cruel. The recent discoveries of a splendid palace at Cnossus and the evidences of a very powerful and splendid kingdom in Crete during the Mycenaean age warrant the belief that the story of Minos contains reminiscences of an early Cretan supremacy in the Ægean. Consult H. R. Hall, *Ægean Archaeology* (New York, 1915). See ARCHÆOLOGY, *Mycenaean Period*; CNOSSUS; CRETE; EVANS, SIR ARTHUR; GOVERNIA.

MINOT, mi'nót. A city and the county seat of Ward Co., N. Dak., 200 miles west-northwest of Grand Forks, on the Mouse River and on the Great Northern and Minneapolis, St. Paul, and Sault Ste. Marie railroads (Map: North Dakota, C 2). It is the seat of a State normal school and contains a public library, attractive courthouse, post office and Federal buildings, and Riverside Park, which is crossed by the river three times. Minot is a distributing centre for a wide area and is engaged in lignite coal mining, flour milling, and the manufacture of briquettes. Ample water power is available, the Mouse falling 10 feet here. The water works are owned by the city. Minot has adopted the

commission form of government. Pop., 1900, 1277; 1910, 6188; 1920, 10,476.

MINOT, CHARLES SEDGWICK (1852-1914). An American anatomist, born at Roxbury, Mass. He graduated at Massachusetts Institute of Technology in 1872, studied biology at Leipzig, Paris, and Würzburg, and took the degree of S.D. at Harvard in 1878. At Harvard Medical School he taught from 1880 till his death, becoming James Stillman professor of comparative anatomy in 1905 and director of the anatomical laboratories in 1912. In 1912-13 he served as Harvard exchange professor at Berlin and Jena. He made important investigations and discoveries in the fields of muscular physiology, respiration, and human embryology. He was president of the American Society of Naturalists in 1894, of the American Association for the Advancement of Science in 1901, and of the Association of American Anatomists in 1904-05, and was corresponding member of various important foreign societies. Honorary degrees were conferred on him by Yale, Toronto, St. Andrews, and Oxford. In addition to many papers and monographs, his publications include: *Human Embryology* (1892), which has been translated into German and is one of the most valuable works on the subject; *A Laboratory Text-Book of Embryology* (1903; 2d ed., 1910); *Age, Growth, and Death* (1908); *Die Methode der Wissenschaft* (1913); *Modern Problems of Biology* (1913; also in French).

MINOT, GEORGE (1817-56). An American jurist, born in Haverhill, Mass. He graduated at Harvard in 1836 and at the law department of that institution in 1838, studied under Rufus Choate, and was admitted to the bar in 1839. He practiced in Boston, took high rank in his profession, and was for many years counsel for the Boston and Maine Railroad. He edited, in association with Richard Peter, Jr., eight volumes of the *United States Statutes at Large* and was sole editor of that work from 1848 to 1856. He published *A Digest of the Decisions of the Supreme Court of Massachusetts* (45 vols., with supplement, 1844-52) and edited *English Admiralty Reports* (9 vols., 1853-54).

MINOT, GEORGE RICHARDS (1758-1802). An American jurist. He was born in Boston, graduated at Harvard in 1778, and soon afterward was admitted to the bar. From 1781 to 1791 he was clerk of the Massachusetts House of Representatives. He was secretary of the convention called to ratify the Federal Constitution. In 1792 he was appointed judge of probate for Suffolk County, in 1799 he was made Chief Justice of the Court of Common Pleas, and from 1800 until his death was judge of the Municipal Court of Boston. Besides editing three volumes of the *Collections of the Massachusetts Historical Society*, of which he was one of the founders, he published a *History of the Insurrection in Massachusetts in 1786* (1786) and a *History of Massachusetts Bay* (1798-1803). The latter work is in continuation of Hutchinson's *History of Massachusetts Bay*.

MINOT, LAURENCE (?1300-752). An English lyric poet, born and bred probably in the northeast midlands of England. He was no doubt a layman. Professor Herford agrees with other scholars in thinking that Minot was probably a soldierly minstrel, who sang also at court. Minot wrote in haste, with the warlike or political events that he describes still fresh in his mind. His style is rough. He is preëminently

a war poet and a patriot, full of love for a united England, though he was himself in all likelihood of Norman origin. He wrote 11 spirited political songs (in the Northern dialect) celebrating the military events of the time. They begin with the *Battle of Halidon Hill* (1333) and close with the *Capture of Guines* (1352). Among the best is *How Edward Came to Brabant* (1339). They exist in only one manuscript (British Museum), discovered by Tyrwhitt. The best editions are *Laurence Minot's Lieder*, edited by William Scholle, in *Quellen und Forschungen* (Strassburg, 1884), and *The Poems of Laurence Minot*, edited by Hall (Oxford, 1887).

MINOTAUR (Gk. Μινόταυρος, *Minótauros*). The bull of Minos (q.v.), according to the Greek legend, son of the wife of Minos, Pasiphaë, and a bull sent by Poseidon. For it she conceived a passion which the skill of Dædalus (q.v.) enabled her to gratify. Her offspring, a human body with a bull's head, was shut up by Minos in the mysterious Labyrinth (q.v.) at Cnosus, where he was fed on human victims. Yearly (or every three or nine years, according to other versions of the story) the Athenians, who had been conquered by Minos, were compelled to send seven youths and seven maidens for this monster, till Theseus (q.v.) slew him. The origin and nature of this story have as yet received no adequate explanation, but the frescoes of the palace at Cnosus showing men and girls performing gymnastic feats upon wild bulls suggest that the origin of the legend is to be sought in dim reminiscences of the Mycenaean bull ring. Some scholars connect the Greek name Λαβύρινθος, *Labyrinth*, with Gk. λαβρός, *labrys*, a double axe, a hieroglyphic or sacred sign of Zeus, which appears everywhere in the palace at Cnosus (consult R. H. Hall, *Aegean Archaeology*, pp. 152-153, New York, 1915); in this view the Labyrinth is the Place of the Double Axe. The bull was sacred in Crete to Zeus. See MINOS.

MINOT'S LEDGE. See LIGHTHOUSE.

MINOTTO, AGNES MITO. See SOBMA, AGNES.

MINSK, minsk. A government of west Russia, in Lithuania, bounded by the Government of Vitebsk on the north, Mohilev and Tchernigov on the east, Kiev and Volhynia on the south, and Grodno and Vilna on the west (Map: Russia, C 4). Area, 35,293 square miles. The northwestern part, about one-fifth of the entire area, is somewhat elevated. It forms the watershed between the Dnieper and the Niemen. The remainder of the government is low, marshy, thickly wooded, and very sparsely inhabited, forming the larger portion of Poliessie (q.v.). Minsk is watered chiefly by the Berezina, the Pripet, and the Niemen; lakes abound in the southern part, and the climate is unhealthy. By the nature of its surface Minsk is not well fitted for agriculture, hence this industry is in a primitive state. Stock raising is favored by the abundance of pasture land. The forests, mostly pine, occupy over one-third of the total area and form one of the chief natural resources of the region. Large quantities of timber are floated to Prussia by the Berezina, the Pripet, and the canal which connects the Dnieper with the Bug, a tributary of the Vistula. Considerable quantities of wood for fuel are exported also to Kiev and used on the local railroads. The extent of this industry may be judged from the fact that about 70,000 people are employed an-

nually in the transportation of the timber down the rivers. Yeast, flour, and wooden products of all kinds are the chief manufactures. The ship-building industry deserves special mention. The government is traversed by two important railways, one connecting Warsaw with Moscow and the other running from the Baltic Provinces to southern Russia. Pop., 1909, 2,755,900; 1913, 2,963,700, composed chiefly of white Russians, Poles, Jews, and Lithuanians. Over 70 per cent of the population belong to the Greek Orthodox church. The government was formed out of part of the territory passing over to Russia on the second partition of Poland in 1793. It consisted till 1843 of 10 districts, but since then nine compose this government. Capital, Minsk.

MINSK. The capital of the Government of Minsk, Russia, situated in a hilly region on the Svislotch, a tributary of the Berezina, 468 miles by rail southwest of Moscow (Map: Russia, C 4). It is an old and irregularly built town, with two cathedrals, of which that of St. Catharine (1611) is especially worthy of mention. Among its educational institutions are two classical Gymnasias and one Realgymnasium, a theological seminary, a museum, and a theatre. Minsk manufactures leather, agricultural implements, soap, tobacco products, etc. The commerce is mostly in agricultural and forest products and leather. A yearly fair is held in March. Minsk is the seat of a Greek Orthodox and of a Roman Catholic bishop. The municipality maintains a pawnshop. Pop., 1904, 97,997; 1910, 105,441, of whom over 50,000 were Jews, about 21,000 Greek Orthodox, 15,000 Roman Catholics, and over 1700 Mohammedans. The town is first mentioned in 1066 as a dependency of the princes of Podolsk. After a short existence as the capital of a separate principality, it fell at the end of the twelfth century into the hands of Lithuania. In 1499 it obtained Magdeburg rights and in 1793 passed to Russia. During the Polish uprising in 1831 several engagements took place in the vicinity of the town, which is the headquarters of the Russian Fourth Army Corps.

MIN'STREL (OF. *menestrel*, *menesterel*, *menestral*, Fr. *menestral*, It. *ministrello*, *menestrello*, from ML. *ministralis*, *ministrel*, retainer, Lat. *minister*, attendant, retainer, minister, from *minor*, less). The term first used in the late thirteenth century to designate a retainer who amused his lord with music and song. It has now come to be the generic name for the poet musician, the verse reciter, the mountebank, merry Andrew, juggler, and acrobat of the Middle Ages, as well as for certain modern entertainers. (See below.) Before the Norman Conquest the professional poet was known in England as a *scōp* (shaper or maker). "Maker" sometimes signified a poet in Shakespeare's time. The *scōp* shaped or composed his own poems, and chanted or sang them to the accompaniment of a rude harp. *Widsith* (i.e., Long Travel), perhaps the oldest of extant English poems (for it is earlier than the Angles' inroad of Britain), is an account of the *scōp*'s wandering and reception among the Huns, Goths, Danes, and other peoples. For the tales he recited in the mead hall the *scōp* was rewarded with many treasures, including golden rings and bracelets. The *scōp* was not commonly a wanderer. He was rather attached to the household of some chief, by whom he was maintained, and in some cases rewarded with gifts of land. The *scōp* was held in great

honor. He composed his poems in solitude and recited them in the hall where his master feasted. The recitation was doubtless accompanied by gesture as well as by music.

The *scōp* was first of all a poet, differing from the modern poet mainly in the fact that he not only shaped but also recited his compositions. His theme was the glorious deeds of his chieftain or of some hero of his race. To him we are indebted for our primitive and narrative poems like *Beowulf*. The spread of Christianity in England broke up the old tribal relation and therefore the standing of the *scōp* was changed. In a rank much beneath the *scōp* were the gleemen, who, though they no doubt sometimes improvised songs and modified the matter that came to them, were satisfied for the most part to render what others had composed. They had no settled abode, but strolled far and near, earning what they could by their minstrelsy. (The accompanying illustrations, derived from medieval manuscripts, give some notion as to the strolling minstrel's looks and demeanor.) Among their accomplishments were tumbling, ropewalking, and feats of jugglery. Some of them chewed stones or appeared to swallow knives or fire. Others had performing animals, such as bears, goats, marmots, dogs, and monkeys.

The Normans brought many *jongleurs* (see **JONGLEUR**) and *troubadours* (q.v.) to England. The minstrels of the Middle Ages were in part descendants of the Teutonic *scōpas* and gleemen who took root in Gaul with the invasion of the Franks, or of those who went along with the

A ROPEWALKER AND JUGGLER.

MINSTREL WITH DRUM, FLAGOLET, AND PERFORMING BEAR.

Teuton invaders into Italy, England, and elsewhere, in part of the *mimi* and *acurra* who had once overrun the Roman Empire. With the Celtic bards they have probably no kindred. At the battle of Hastings, Taillefer, minstrel and warrior, rode before the Norman chivalry, tossing his shield aloft, and stirring their courage with the Song of Roland, and there bravely met his death. By the fourteenth century the poet and the performer in England were usually dis-

tinct. The sc6p and the troubadour were transformed into poets like Chaucer and Gower. True, there still survived in the structure of their tales several devices of the singers, such as the address to an audience, but the audience was wholly imaginary. The gleemen and jongleurs

MINSTREL PLAYING A REBEC.

were then known as minstrels, of whom the more reputable were still held in great honor. At feasts and festivals they swarmed in great numbers with harps, fiddles, bagpipes, flutes, flageolets, citterns, and kettledrums. Such an occasion is described by Chaucer in the Squire's Tale: As Cambuskan dines, the "minstralles" play "beforn him at the bord deliciously." When he goes out he is preceded by "loude ministralcye,"

Ther as they sownen diverse instruments
That it is lyk an heven for to here.

But the decline of minstrelsy had already set in, as we know from Langland's *Piers Plowman*, the best single source of information for England. Minstrels as a class Langland severely satirized, calling them prattlers and buffoons, foul and scurrilous of speech, indeed the very children of Satan. Yet in England minstrels may have had a closer connection with genuine poets than they had on the Continent, where from the outset these sons of the Roman *mimi* and *scurrie* (cf. "scurrilous") and of the old bards of the North were abhorred by the Church. Mass and absolution were denied them; indeed, they were under perpetual excommunication and were assured that they would spend eternity at the bottom of hell. Nor had they—on the Continent, at all events—any standing before the secular law. Those who harmed them went unpunished; yet if a minstrel was ill handled he had the privilege of beating the shadow of his offender. As early as 1321 the minstrels of Paris were formed into a guild, and in 1469, in England, a guild of royal minstrels was organized, which minstrels throughout the realm were compelled to join, if they were to ply their trade (or their art) legally.

Most minstrels were itinerant; others were retained by lords as jesters. Not seldom they were women, or, at all events, women followed many a band of minstrels and lived their hard and dissolute life. The very name of minstrel was a byword, but everywhere they were wel-

come. After the invention of printing there was little place for the minstrel as an intermediary between author and public. He gradually found his main occupation as a ballad singer at street corners or at the wassails of the more ignorant barons. Musicians still continued, it is true, to be retained at court, and ample provision was made for their maintenance. But by an act of Parliament in the thirty-ninth year of Elizabeth's reign "minstrels abroad" were classed as "rogues and vagabonds," and were ordered to be punished as such.

In spite of new social conditions, minstrelsy was slow in dying out. George II maintained a company of 24 musicians, who were employed in the service of the Chapel Royal and in rendering odes on birthdays and New Year's. Scott, as is well known, collected the minstrelsy of the Scottish border, consisting of traditional ballads that were still recited; and in the *Lay of the Last Minstrel* is described a wandering harper who is supposed to have lived at the close of the seventeenth century. Recently, too, W. B. Yeats has discovered "the last gleeman in Ireland," a certain Michael Moran, blind almost from birth. "He was," says Yeats, "a true gleeman, being alike poet, jester, and newsman of the people."

A KING MINSTREL.
Head of a minstrel troupe.

The descendant of the old gleeman, it is said, is still not unknown in the Orkneys.

American Minstrels. Towards the beginning of the nineteenth century a new type, the Southern negro, appeared on the American stage. At first he was accepted merely as a comic character, but gradually his songs and eccentricities overshadowed his personal characteristics and he began to be looked upon as a "feature" in the performance. Before the advent of Thomas D. Rice, the reputed founder of negro minstrelsy, there had been a score of actors who, as negro comedians, had sung and danced their way into popular favor; but Rice was the first minstrel whose performance received universal recogni-

tion. His most famous character, Jim Crow, was drawn from life, its original being an old Louisville slave. In 1836 Rice went to England, where he duplicated his American successes. Individual negro minstrels now became very numerous, and in 1843 the first company, the Virginia Minstrels, was formed. It consisted of "Dan" Emmett, Frank Brower, "Billy" Whitlock, and "Dick" Pelham. The style of performance adopted by them has remained much the same ever since, for they danced, sang, played their instruments, and carried on a running dialogue of jokes. Among the more famous bands of minstrels may be mentioned: White's Kitchen Minstrels, his Virginia Serenaders, his New York Minstrels; Christy's Minstrels, which made a tremendous sensation; Bryant's Minstrels, Wood's Minstrels, and the companies formed by "Tony" Pastor, Thatcher, Primrose, Dockatader, West, Buckley, Backus, Birch, and Bailey. Minstrel performances are usually of one general character. The performers, who are always men and who number from 15 to 40, sit in a semicircle. At either end sit the "end men," or "bones," while in the middle of the line is the "interlocutor," who gravely asks his companions, especially the "end men," such questions as shall bring out their stock of jests. Each member of the troupe takes some part in the performance. The minstrel's characteristic instruments are the guitar, the banjo, tambourine, and the "bones," which are two pairs of ebony sticks, about 1 inch wide and 8 inches long, and are clapped together in the performer's fingers.

MINSTREL, HENRY THE. See HENRY THE MINSTREL.

MINSTREL BOY, THE. A favorite song in Moore's *Irish Melodies*. The music is that of "The Moreen," an old Irish air.

MINT (AS. *mynet*, *mynit*, *mynyt*, from Lat. *moneta*, mint, epithet of Juno, whose temple at Rome was the mint, from *monere*, to warn). An establishment for making coins or metallic money. See MONEY.

The earliest regulations regarding the English mint belong to Anglo-Saxon times. An officer called a reeve is referred to in the laws of Canute

as having some jurisdiction over it, and certain names which, in addition to that of the sovereign, appear on the Anglo-Saxon coins, seem to have been those of the moneyers, or principal officers of the mint. Besides the sovereign, barons, bishops, and the greater monasteries had their respective mints, where they exercised the right of coinage, a privilege enjoyed by the archbishops of Canterbury as late as the reign of Henry VIII and by Wolsey as Bishop of Durham and Archbishop of York.

After the Norman Conquest the officers of the royal mint became to a certain extent subject to the authority of the exchequer. Both in Saxon and Norman times there existed, under control of the principal mint in London, a number of provincial mints in different towns of England; there were no fewer than 38 in the time of Ethelred, and the last of them were only done away with in the reign of William III. The officers of the mint were formed into a corporation by a charter of Edward II; they consisted of the warden, master, comptroller, assay master, workers, coiners, and subordinate.

The seigniorage or coining charge at one time formed a considerable item in the revenues of the crown. It was a deduction made from the bullion coined, and comprehended both a charge for defraying the expense of coinage and the sovereign's profit in virtue of his prerogative. In the reign of Henry VI the seigniorage amounted to 6d. in the pound; in the reign of Edward I, 1s. 2½d. The seigniorage on gold was abolished during the reign of Charles II and has never since been exacted. The shere, or remedy, as it is now called, was an allowance for the unavoidable imperfection of the coin.

A new mint was erected on Tower Hill in 1810. In 1815 some alterations were made in the constitution of the mint, and in 1851 a complete change was introduced in the whole system of administration. The control of the mint was vested in a master and deputy master and a comptroller. The mastership, which had in the early part of the last century become a political appointment held by an adherent of the government, was restored to the position of a permanent office, the master being the ostensible executive head of the establishment. Further changes were made in the administration of the mint in 1869. The mastership was added to the duties of the Chancellor of the Exchequer, without any addition of salary, and the offices of deputy master and comptroller were amalgamated.

Colonial branches of the mint were established at Sydney in 1853, at Melbourne in 1869, and at Perth in 1899 to coin the gold so largely found in Australia, but the silver currency for the Australian Commonwealth has been imported from the Royal Mint, London. Arrangements were made for a silver coinage to be struck in the Commonwealth. A branch of the Royal Mint has been maintained at Ottawa, Canada, since 1908.

The first mint in the United States was established at Philadelphia by the Coinage Act of April 2, 1792; the first production of the new mint was the copper cent of 1793. Silver dollars were first coined in 1794 and gold eagles in 1795. In 1915 there were three coinage mints, located at Philadelphia, San Francisco, and Denver, respectively, and also a mint at New Orleans, where, however, there had been no coinage after 1909 although bullion is received

upon the same terms as at the assay offices. Assay offices are located at New York, Carson City, Helena, Boise, Charlotte, St. Louis, Deadwood, and Seattle. The Act of April 1, 1873, put all the mints and assay offices on the same footing as a bureau of the Treasury Department, under the superintendence of the Director of the Mint, who is appointed by the President for a term of five years and is subordinate to the Secretary of the Treasury. The Philadelphia mint has an engraver who supervises the manufacture of the dies used in all the United States mints.

Processes of Coining. Down to the middle of the sixteenth century little or no improvement seems to have been made in the art of coining from the time of its invention. The metal was simply hammered into slaps, which were afterward cut up into squares of one size and then forged round. The required impression was given to these by placing them in turn between two dies and striking them with a hammer. As it was not easy by this method to place the dies exactly above each other, or to apply proper force, coins so made were always faulty and had the edges unfinished, which rendered them liable to be clipped. The first great step was the application of the screw, invented in 1553 by a French engraver named Brucher. The plan

year the government institutions issued 2,033,780 fine ounces of silver bars as compared with 28,903,010 fine ounces from private refineries for use in the industrial arts. A depositor may bring crude gold bullion in any quantity, of \$100 or more in value, and receive either fine gold bars or coin, at his option, a charge of not more than five cents an ounce being made for assaying and refining. For the silver alloy in the gold the owner will be paid at the market value of silver.

If the gold or silver is to be coined into money the pure bars must be mixed with copper alloy; standard coin is composed of 900 parts of gold (or silver) and 100 parts of purest copper in 1000. The law allows a slight variation from this standard, but in actual practice a single gold coin rarely varies more than 0.03 per cent from the standard, either way, and a silver coin, not more than 0.1 per cent, while the average is almost exactly correct. Weighed quantities of gold and copper, or of silver and copper, are melted together in a black-lead crucible, the molten metals thoroughly stirred together, and then poured into cast-iron molds to form ingots. These vary in size according to the denomination of the coins to be made from them. The following table gives the sizes and approximate weights of gold ingots:

DENOMINATIONS	Approximate weight in ounces	Length in inches	Thickness in inches	Width in inches
Double eagles.....	80	12½	½	1½
Eagles.....	62	11½	½	1½
Half eagles.....	40	12	½	1½
Quarter eagles.....	33	12½	½	1½

was found expensive at first, and it was not till 1662 that it altogether superseded the hammer in the English mint.

The following description of the method of coining money is based on a pamphlet, *Mint Processes of the United States*, issued by the Treasury Department. The processes required for converting the crude metal into money are: (1) assaying; (2) refining or parting, which reduces the material into ingots or bars of standard purity; (3) reducing the bars to coinage ingots by mixing with them the proper amount of copper alloy; (4) coining, or transforming the coinage ingots into money. The gold and silver which are brought to the mint may be in a crude or manufactured condition and are of varying degrees of fineness. The initial process, therefore, is to assay the metal, in order to determine both its value and the subsequent minting operations necessary to refine it. This process and the succeeding one of refining are described in the metallurgical articles on GOLD and SILVER and under ASSAYING. The bullion thus purified is reduced to bars, a gold bar usually weighing 400 ounces, worth about \$8000. It is now ready to be used for industrial purposes, or for the next stage in the coinage process.

The consumption of gold and silver in the arts and industries is very great. During the fiscal year 1914 the Director of the United States Mint reported that gold bars for industrial use were manufactured in the various mints and assay offices, principally those of Philadelphia and New York, to the coinage value of \$39,767,944. Private refineries furnished \$3,455,841 more. These bars are 0.999 fine. In the same

The ingot for silver-dollar coinage is 1½ inches wide, ½ inch thick, and 12½ inches long. The ingots are passed repeatedly between heavy rollers to form them into strips, a process which is called "breaking down." After each passage the rollers are screwed tighter, the amount of pressure being regulated exactly by a clock dial. Having been reduced to the proper thickness, the strips are cut into planchets by means of a steel punch working into a matrix. (See DIES AND DIE SINKING.) These planchets are now cleaned and carefully sorted, all that are not perfect or are under the standard weight being set aside to be remelted, while those that are above weight are filed down. The standard weight for gold coins is as follows: Double eagle, 516 grains; tolerance allowed by law, 0.50 grain. Eagle, 258 grains; tolerance, 0.50 grain. Half eagle, 129 grains; tolerance, 0.25 grain. Quarter eagle, 64.5 grains; tolerance, 0.25 grain.

Next comes the process of milling, or producing a raised rim around the edge of the coin, to prevent abrasion. This is accomplished in a milling machine, into which the blanks are fed automatically. The blanks rotate in a horizontal plane in a groove formed on one side by a revolving wheel and on the other by a fixed segment of corresponding groove. Each piece, as it passes through this narrow groove, has its edges forced up into an even rim. After annealing and cleaning, the coins are now ready for the final process of stamping. The planchet, fed to the press through a vertical tube, is automatically placed in a steel collar, whose inner surface is reeded to produce the fluted surface on the milled edge of the coin. Here it is firmly held while the dies close upon it

with enormous force, producing impressions on both sides of the coin. (This process and the preparatory one of engraving and stamping the dies are described under DIES AND DIE SINKING.) The pressure required to produce a clear, sharp impression on the various gold coins is as follows: double eagle, 175 tons; eagle, 120 tons; half eagle, 75 tons; quarter eagle, 40 tons. Double eagles and eagles are struck at an average rate of 80 per minute; half eagles and quarter eagles at a rate of 100 per minute. The pressure required for stamping silver coins is: dollar, 150 tons; half dollar, 110 tons; quarter dollar, 80 tons; dime, 40 tons. The first three are struck at an average rate of 80 per minute, and dimes at the rate of 100 per minute.

The total coinage of gold by the mints of the United States from 1792 to June 30, 1914, was \$3,337,566,310.50.

The domestic coinage for the fiscal year 1914 in the mints of the United States amounted to 199,934,493 pieces, having a value of \$36,047,386.24. The seigniorage on the coinage of silver dollars, subsidiary and minor coins during that year amounted to \$5,661,266.58. (See SEIGNIORAGE.) During 1914 the coinage in the mints of the United States was: gold, \$26,825,810; silver, \$6,240,219.45, and minor coins of nickel and bronze, \$3,181,356.79. In comparison with the coinage of the United States it may be stated that in 1913 Canada coined \$1,986,480 of gold and \$1,327,139 of silver; Great Britain, \$27,586,817 of gold, equivalent to \$134,251,245, and silver valued in United States money at \$8,240,094. France in the same year coined 246,281,160 francs of gold, valued in United States money at \$47,532,234, and silver valued in United States money at \$4,179,250. Germany coined 143,525,760 marks in gold, valued at \$34,173,483, and silver valued in United States money at \$12,168,426. The total gold coinage for the world in 1913 was valued at \$318,773,474, of which \$3,372,866 was recoinage. The total coinage of silver in the same year was valued at \$178,301,517, representing 158,557,652 fine ounces, and of this amount \$21,415,372, or 19,324,926 fine ounces, was recoinage. Consult the annual reports of the Director of the Mint and also the various pamphlets on coinage issued by the Treasury Department at Washington. See COINAGE; MONEY.

MINT (AS. *mintē*, Icel. *mintā*, OHG. *minza*, *munza*, Ger. *Minze*, *Münze*, from Lat. *menta*, *mentha*, from Gk. *μίνθα*, *mintha*, *μίνθη*, *minthē*, mint), *Mentha*. A genus of plants of the family Labiatae. The species are perennial herbs, varying considerably in appearance, but all with creeping rootstocks. The flowers are whorled, the whorls often grouped in spikes or heads. The species are widely distributed over the world; some of them are very common. Water mint (*Mentha aquatica*) grows in wet grounds and ditches, and corn mint (*Mentha arvensis*), which abounds as a weed, in European fields and gardens. These and most of the other species have erect stems. All the species contain an aromatic essential oil, in virtue of which they are more or less medicinal. The most important species are spearmint, peppermint, and pennyroyal; spearmint or green mint (*Mentha spicata*), a native of almost all the temperate parts of the globe, has erect, smooth stems, from 1 foot to 2 feet high, with the whorls of flowers in loose cylindrical or oblong spikes at the top; lanceolate, acute, smooth,

serrated leaves, destitute of stalk, or nearly so. It has a very agreeable odor. Peppermint (*Mentha piperita*), a plant of equally wide distribution in the temperate parts of the world, is very similar to spearmint, but has stalked leaves and flowers in short spikes, the lower whorls somewhat distant from the rest. It is very readily recognized by the peculiar pungency of its odor and of its taste. Pennyroyal (*Mentha pulegium*), also very cosmopolitan, has ovate, stalked leaves, a much-branched prostrate stem, which sends down new roots as it extends in length, and the flowers in distant globose whorls. Its smell resembles that of the other mints. All these species, in a wild state, grow in ditches or wet places. All are cultivated in gardens. The American pennyroyal is *Hedeoma pulegioides*. It grows in dry soils. Mint sauce is generally made of spearmint, which is also used for flavoring soups, etc. A kind of mint with lemon-scented leaves, called bergamot mint (*Mentha citrata*), is found in some parts of Europe, and is cultivated in gardens. Varieties of peppermint and horsemint (*Mentha longifolia*), with crisped or inflated rugose leaves, are much cultivated in Germany under the name of curled mint (*Krauseminze*); the leaves are dried and used as a domestic medicine and in poultices and warm baths. All kinds of mint may be easily propagated by division of the roots or by cuttings.

Peppermint, pennyroyal, and spearmint are used in medicine. The pharmacopoeias contain an *aqua*, *spiritus*, and *oleum* of each of them, the officinal part being the leaves and stems, which should be collected when in flower. Peppermint is extensively used to flavor candy and in mixtures to cover the taste of drugs. Nearly one-half of the oil of peppermint and spearmint now used in the world is produced and distilled in Michigan, the great seat of this industry being in St. Joseph County.

MINT FAMILY. A family of plants. See LABIATAE.

MINTO, GILBERT ELLIOT, first EARL OF (1751-1814). A British diplomat and administrator. He was educated in Paris and at Edinburgh and Oxford and was called to the bar in 1774. In 1776 he entered Parliament as a Whig. From 1794 to 1798 he was Viceroy of Corsica. In 1797 he was created Baron Minto, and he was Ambassador to Vienna (1799-1801). On his reappearance in the House of Lords he became an advocate of the union of Ireland with England, and afterward strenuously opposed Roman Catholic emancipation. He was Governor-General of India from 1807 to 1813; did much to suppress internal disorder in the regions under his government; annexed the island of Amboyna in 1809, the Molucca Islands in 1810, and Java in 1811; and he captured the Isle of Bourbon and the island of Mauritius from the French in 1810. Consult: *The Life and Letters of Lord Minto*, edited by the Countess of Minto, his great-niece (3 vols., London, 1874); id., *Lord Minto in India* (ib., 1880).

MINTO, GILBERT JOHN, fourth EARL OF (1847-1914). A British administrator. He was educated at Eton and at Trinity College, Cambridge, and entered the Scots Guards as an ensign in 1867, resigning in 1870. He served with the Turkish army (1877), in the Afghan War (1879), and was private secretary to Sir Frederick Sleigh (afterward Earl) Roberts in Cape Colony (1881). He was a volunteer in

the Egyptian campaign conducted by Sir Garnet (afterward Field Marshal Lord) Wolseley; was military secretary to the Marquis of Lansdowne, Governor-General of Canada (1883-85); and was chief of staff to Sir Frederick Middleton during the second Riel rebellion (1885). He returned to England and in 1886 was an unsuccessful candidate for the House of Commons. Later he was Governor-General of Canada (1898-1904) and Viceroy of India (1905-10).

MINTO, WILLIAM (1845-93). An English literary critic. He was born at Alford, Scotland, and graduated at Aberdeen in 1865. He edited the London *Examiner* from 1874 to 1878 and in 1880 became professor of logic and English literature at Aberdeen. He wrote three stories, *The Crack of Doom* (1886); *The Mediation of Ralph Hardelot* (1888), and *Was she Good or Bad?* (1889), but is chiefly known as a critic. In this latter field he published many well-known works, including: *Manual of English Prose Literature, Biographical and Critical* (1872); *Characteristics of English Poets from Chaucer to Shirley* (1874); *Daniel Defoe*, for the "English Men of Letters Series" (1879). There appeared posthumously *University Extension Manual on Logic* (1893); *Plain Principles of Prose Composition* (1893); *English Literature under the Georges* (1894). Original in method, he ably defended many novel hypotheses.

MIN'TON, THOMAS (1765-1836). An English pottery manufacturer, originally an engraver, who worked for Spode in London and in 1791 established a plant of his own at Stoke-upon-Trent, where he made principally majolica and reproductions of the works of Della Robbia and Palissy. The business was continued by his son, Herbert (1793-1858), and was incorporated in 1883. During the latter half of the nineteenth century, under the artistic direction of Leon Arnoux of the old family of French potters, Minton porcelain compared favorably with that produced at Sèvres. See POTTERY; PORCELAIN.

MINUCIUS FELIX. See FELIX, MARCUS MINUCIUS.

MINUET, mīn'ū-ēt' (Fr., small, dim. of *menu*, from Lat. *minutus*, small, p.p. of *minuere*, to diminish, from *minor*, less; connected with Gk. *μῦρος*, *minyros*, small, Skt. *mī*, to make small, Goth. *minniza*, OHG. *minniro*, Ger. *minder*, AS., archaic Eng. *min*, less; so called because of the small steps taken in the dance). A graceful and stately dance of French origin. It is supposed to have originated in Poitou and was introduced into Paris in 1650. The first-known minuet tunes were written by Lully (q.v.) in 1653. The minuet was a favorite at the court of Louis XIV and in the reign of Charles II was carried over into England, where it continued popular until the time of George II. In Russia it flourished during the reigns of Peter the Great and Catharine II. At first the minuet was in three-quarter time and consisted of two eight-bar phrases, each of which was repeated. Mozart's minuet in *Don Giovanni* shows the form of the early dance. It was soon, however, extended by the addition of a second movement (written in three-part harmony and hence called trio) and by increasing the number of bars. Bach and Handel often introduced the minuet into their suites. Those of the former are especially famous, and Handel also used it as a concluding movement for operatic and oratorio

overtures. The minuet is of particular importance because of the position it occupies in the history of the symphony, which is an evolution of the suite. Haydn was the first to employ it in the symphony, but he changed its character by quickening the time and making it vivacious rather than stately. Mozart used Haydn's form, retaining the rapid *tempo*, but gave it a tender, graceful significance. With Beethoven its history practically ceases, for he transformed it into the *scherzo*, thus making it an integral part of the symphony. Its use by later composers, Schumann, Mendelssohn, and others, is comparatively rare. See DANCING; SUITE; SYMPHONY.

MINUIT, mīn'ū-it, PETER (1580-1641). An early governor of New Netherland. He was born in Wesel, on the Rhine; was a deacon for a time in the Protestant or Walloon church there; removed to Holland early in the seventeenth century; and in December, 1625, received from the Dutch West India Company the appointment of Governor and Director General of New Netherland. He reached Manhattan Island May 4, 1626, and soon afterward purchased the island from the Indians, obtaining it for the sum of 60 guilders (about \$24). He built Fort Amsterdam, defended with great courage and determination the claim of the Dutch to rightful possession of the island, and administered the affairs of his office judiciously and to the general satisfaction of the colony. The fact that the patroons were successful in establishing titles to enormous tracts of land became objectionable to the Dutch West India Company, who placed the responsibility on the shoulders of Minuit. In 1631 he was accordingly recalled by the company, and sailed for Holland in the following spring, but was driven into Plymouth, England, by a gale. Here he was charged with having prosecuted illegal trading within English dominions, and his vessel was attached on complaint made by the Council for New England. In May, however, his vessel was released. Minuit made every effort to reestablish himself in the favor of the Dutch West India Company, but without success, and finally offered his services to the government of Sweden. Through the influence of Oxenstiern, then Chancellor, a Swedish West India Company was organized and Minuit was commissioned to establish a Swedish colony in America. He accordingly gathered together a sufficient number of Swedes and Finns for this purpose, sailed from the port of Gothenburg, Sweden, in 1637, and early in 1638 built Fort Christiana, near where the city of Wilmington, Del., now stands. The Swedish colonization scheme was bitterly opposed by the Dutch, who threw every obstacle in the way of its success, and eventually captured the colony and annexed it to their possessions in 1655. Consult Kapp, "Peter Minnewet aus Wesel," in *Historische Zeitschrift*, vol. xv (Munich, 1806), and J. J. Mickley, "Some Account of William Usselinx and Peter Minuit," in the *Delaware Historical Society Papers* (Wilmington, 1881).

MINUSINSK, mē-nū-sēnsk'. A town of southern Siberia, in the Government of Yeniseisk, situated on the Yenisei, 300 miles southeast of Tomsk. It has a high school for girls, a good museum and library, and considerable trade in grain, cattle, and placer gold. The neighboring country is rich in coal, iron, and salt lakes. Pop., 1897, 10,255; 1911, 15,584. Minusinsk is also the capital of a district bear-

ing the same name, with an area of 43,388 square miles and a population in 1912 of 257,800.

MINUTE, min'it (OF., Fr. *minute*, from Lat. *minutum*, small portion, from *minuere*, to make small). A term applied to the sixtieth part of an hour and to the sixtieth part of a degree of a circle. In architecture the term "minute" is applied to the sixtieth part of the diameter of the shaft of a classic column, measured at the base; it is used as a measure to determine the proportions of the order.

MINUTEMEN. In American history, those civilians, in Massachusetts and several other colonies, who, on the approach of the Revolutionary War, pledged themselves to take the field at a minute's notice. In Massachusetts they were enrolled in pursuance of an Act of the Provincial Congress passed Nov. 23, 1774.

MINUTOLI, mé-nōō'tō-lē, HEINRICH, BARON MENU VON (1772-1846). A Prussian officer and archaeologist. He was born in Geneva of an old Italian family, early entered the Prussian army, and distinguished himself in 1793 in the Rhenish campaign against France, being severely wounded at Bitach. After his recovery Frederick William III promoted him to be major general, and in 1820 made him head of the Prussian archaeological expedition to Egypt. In 1822 he was made a member of the Academy of Sciences. His valuable Egyptian collection was bought for the Berlin Museum by the King of Prussia. Minutoli's last years were spent in retirement at Lausanne. He wrote: *Ueber antike Glasmosaik* (1814), with Klapproth; the important *Reise zum Tempel des Jupiter Ammon und nach Oberägypten* (1824-27); *Ueber die Anfertigung und Nutzung der farbigen Gläser bei den Alten* (1837); *Betrachtungen über die Kriegskunst* (1810); *Beiträge zu einer künftigen Biographie Friedrich Wilhelm III.* (1838-44); *Der Feldzug der Verbündeten in Frankreich, 1792* (1847).

MINYAS (Gk. Μινύας, *Minyas*). A legendary hero connected with the Bœotian city Orchomenos (q.v.). He is called son of Poseidon in the earlier writers, but in Pausanias his father is Chryses, and he is famed for his riches and as builder of the first great treasury—really the domed tomb of Orchomenos. His fame in legend is connected with the fate of his three daughters, Leucippe (or Leuconœ), Arsippe (or Arsinoë), and Alcathe, who, refusing to take part with the Mænads in the orgies of Dionysus, were visited by the god with Bacchic madness, in which they tore to pieces the young son of Leucippe. Their story was acted at the festival of the Agrionia, where the priest of Dionysus, with a drawn sword, pursued women of the family of the Minyade. The Argonauts from Iolcos in Thessaly were also called *Minyæ*, but the original connection with Minyas is very doubtful, and the statements of the ancients are obviously mere attempts to explain the identity of name. Consult Ovid, *Metamorphoses*, iv, 1 ff., 389 ff., and W. H. Roscher, *Lexikon der griechischen und römischen Mythologie*, vol. ii (Leipzig, 1890-97).

MI'OCENE EPOCH (from Gk. μέλιον, *meiōn*, less + καιρός, *kainos*, new). A division of geologic time following the Oligocene and preceding the Pliocene epochs of the Tertiary period. It is represented along the Atlantic coast of North America by a belt of unconsolidated sands and clays that begins in Martha's Vineyard but is concealed in the interval between there and New Jer-

sey. From that State southward to Florida the beds are continuous and also extend to the west along the Gulf coast into Texas, where they attain a thickness of 1500 feet. In the south they include compact limestones and conglomerates. In California extensive gravel beds were laid down along the streams that flowed west from the Sierras and these gravels form the so-called "deep" and "bench" gravels which are worked for gold. The coasts of California, Oregon, and Washington were still largely submerged and marine deposits were formed in that section. In the interior region are found fresh-water strata of Miocene age, including the John Day beds of eastern Oregon, which contain also volcanic tuffs and ashes and which are from 3000 to 4000 feet thick, and the Loup Fork stage of Montana, South Dakota, and the region southward as far as Mexico. Miocene time was characterized by extensive geographical changes through volcanic activity and regional upheaval. Near the close of the epoch North and South America were finally joined together by the upraising of the Isthmus of Panama, the West Indies were elevated, and the coastal lands of the United States were increased by the emergence of the belt from New Jersey to Texas. Notable changes likewise took place in Europe, such as the joining of Spain and Africa and the final severance of connection between the Mediterranean and the Indian Ocean.

The life of the Miocene included many forms of very modern aspects. Among the larger mammals are mastodons, camels, rhinoceroses, and early forms of the ruminants, from the fresh-water beds of the western region. The horse family was represented by *Protokippus* and *Hippotherium*, larger than the Eocene horses but still possessing three toes. In the marine beds are found whales, dolphins, and numerous invertebrates. Consult: "Correlation Papers—Neocene," in *United States Geological Survey Bulletin*, No. 84 (Washington, 1892); Report on "Miocene," *Maryland Geological Survey* (Baltimore, 1904); Chamberlin and Salisbury, *Geology*, vol. iii (New York, 1907). See GEOLOGY: TERTIARY SYSTEM.

MIOGA, mé-yō'gā. See ASARABACCA; GINGER.

MIOHIPPIUS (from Eng. *miocene* + Gk. ἵππος, *hippos*, horse). A name sometimes used to designate the Upper Miocene stage of evolution of the horse, represented by the genus *Anchitherium*. See HORSE, FOSSIL.

MIOLAN, myō'lān', FÉLIX. A name sometimes used by the French singer Marie Caroline Félix Carvalho (q.v.).

MIONNET, myō'nā', THÉODORE EDMÉ (1770-1842). A French numismatist, born in Paris, where he studied in the Collège du Cardinal le Moine and in the Ecole de Droit. After four years of legal practice and a short term in the army, from which he retired because of illness, he became assistant in 1800 in the numismatic cabinet in the Bibliothèque Nationale, and there began to catalogue the collections. He traveled in Italy, made many valuable numismatic finds, and in 1830 was elected to the Academy of Inscriptions. His great works, which still have a distinct scientific value, are *Description des médailles antiques, grecques et romaines* (17 vols., 1806-30) and *De la rareté et du prix des médailles romaines* (1815; 3d ed., 1847). Consult C. A. Walckenaer, *Notice historique sur la vie et les ouvrages de M. Mionnet* (Paris, 1846).

MIOT DE MÉLITO, myō de mā'lē'tō', ASAR

FRANÇOIS, COUNT (1762-1841). A French statesman and writer, born at Versailles. Entering the administration of the French War Department, he remained there when the Revolution broke out, although he upheld the principles of constitutional monarchy. In 1793 he was made Secretary General for Foreign Affairs and two years later was sent as French Envoy to Florence. In the following year he went to Corsica to aid Joseph Bonaparte in the pacification of that island after its evacuation by the British. Returning to Paris in 1798, he was Secretary General of the War Department and a councillor of state under the Consulate. From 1806 to 1813 he served with Joseph Bonaparte in Italy and in Spain. In 1814 he was created Comte de Mérito. He served with Napoleon during the Hundred Days and then retired from public life. His translation of Herodotus (3 vols., 1822) and Diodorus (7 vols., 1835-38) gained him admission to the French Academy. His *Mémoires sur la consolat, l'empire, et le roi Joseph* (3 vols., 1858) appeared in an English translation by Mrs. C. Hoey and J. Lillie in 1881.

MIOTICS. Those drugs which produce contraction of the pupil of the eye. They act by stimulating the terminal filaments of the third or motor oculi nerve and paralyzing the filaments of the sympathetic nerve. The principal miotics are eserine and pilocarpine, used locally by eye surgeons, and morphine, and nicotine, which produce miosis when taken internally in poisonous doses. Drugs which produce dilatation of the pupil are called mydriatics (q.v.).

MIQUEL, mè-kèl', JOHANNES VON (1828-1901). A German statesman, born in Neuenhaus, Hanover, of a family of French émigrés, and educated for the bar at Heidelberg and Göttingen (1846-50). In his student days he was a rabid revolutionist and something of a Socialist, but when the period of reaction set in he soon forsook his earlier sentiments. His practice in Göttingen was very successful, and in 1864 he was elected a member of the Lower House of the Hanoverian Diet and in 1865 burgomaster of Osnabrück. Removing to Berlin in 1870, he was a director of the Diskontogesellschaft until 1873, and then president of its advisory board until 1876. Then he was again made chief burgomaster of Osnabrück and in 1880 of Frankfurt-on-the-Main. But his greater field of usefulness was in the Prussian House of Deputies (to which he was elected in 1867) and in the Imperial Diet (1887-90). There, as in the Prussian House of Lords, of which he was ex officio a member as chief burgomaster of Frankfurt, he was a leader of the National Liberal party and one of Bismarck's most able and forceful lieutenants. In 1890 he became Prussian Minister of Finance, and was hailed as the "Emperor's man," no doubt to reassure the country in face of its fear that the new Imperial policy was to be reactionary. In this office, which Miquel held up to a few months before his death, he showed himself an able financier and a bold reformer in his attempt to liberate the Imperial treasury from depending on the contributions of the various states. As a politician he was an opportunist and sacrificed his convictions in the hope that he might be made Chancellor. But if he was unsuccessful in his programme of Imperial finance, in his more proper sphere of Prussian finance, by playing somewhat into the hands

of the Agrarian party, he secured the adoption of a new tax system which greatly benefited the working classes and at the same time tremendously increased the revenue. He was ennobled in 1897. On his Prussian policy, consult Zedlitz und Neukirch, "Miquel als Finanz- und Staatsminister," in *Preussische Jahrbücher* (Berlin, 1901).

MIQUELON, mîk'e-lôn' or mè'k'lôn'. An island near Newfoundland. See SAINT PIERRE AND MIQUELON.

MIR, mër (Russ., OChurch Slav. *mirŭ*, union, peace, world, Lith. *mera*, Alb. *mir*, peace). The name of the civil communities of the Russian peasants. All land is held in common and is divided, usually according to the number of males at the last census, being redistributed whenever necessary. Each family receives meadow, forest, and arable land, the meadow being sometimes kept in common and only the grass divided. The mir, or village commune, as a body is assessed for taxes by the central government, and the burden of taxation is distributed among the heads of families, according to the amount of land occupied by each. Each mir is self-governing, with elected officers, and adjoining mirs may be grouped in volasts, or small cantons. The system is very old, but is gradually changing, as a mir may now go over to private ownership of land and inheritance of property on vote of two-thirds of its members. Consult Keussler, *Zur Geschichte und Kritik des bäuerlichen Gemeindebesitzes in Russland* (St. Petersburg, 1876-87), and D. M. Wallace, *Russia* (new ed., New York, 1905).

MIRABEAU, mè'ra'bô', GABRIEL HONORÉ RIQUETI, COUNT DE (1749-91). A French orator and statesman. He was the second son of Victor Riqueti, Marquis de Mirabeau, a celebrated economist, and was born at Bignon, near Nemours, March 9, 1749. After several years of private instruction the young Mirabeau was placed (1767) in a fashionable military school in Paris, where he became proficient in languages and in the accomplishments of good society. In 1767 he joined the Berry cavalry regiment and the next year he received a second lieutenant's commission, but his freaks of conduct and his love affairs, one of which brought him into rivalry with his colonel, caused his imprisonment in the citadel of the island of Ré, from which he was released, at his father's request, in March, 1769. The condition of his release was that he should join the expedition to Corsica, and as a member of the Legion of Lorraine he served with credit in the subjugation of that island. In 1771 he was commissioned captain of dragoons and in 1772 he was married at Aix to Marie Emilie de Covet, only daughter of the Marquis de Marignane. Of this union one son, Victor, was born in 1773, but he died in 1778. Debts, quarrels with his father and wife, and an altercation with the Marquis de Villeneuve-Monans led to his imprisonment by *lettre de cachet* in the castle of If in 1774. Mirabeau even during his imprisonment managed to fall violently in love with the young Marquise de Monnier; trouble ensued, and he finally escaped to Switzerland, where he was joined by Sophie, as he called his mistress, and in October, 1776, they settled in Amsterdam, where Mirabeau gained a livelihood as a hack writer. In the meantime the French courts passed sentence upon the runaway lovers, who were arrested in May, 1777, and brought to

Paris, where Sophie was kept under close surveillance, while Mirabeau was imprisoned at Vincennes. For three years and a half he was kept in close confinement, but through his guard, a brother Freemason, he was able to carry on his famous correspondence with Sophie. As a prisoner he devoted himself to the translation of numerous classics and to the production of various original works, some of which were later published. After his release in December, 1780, he forsook Sophie, who, after another love affair, committed suicide in 1789. Then he returned to Pontarlier, secured the revocation of the death sentence, which had been passed on him for the seduction of Sophie, and later went to Aix, where, after a trial in which he ably conducted his own suit, he separated from his wife in 1783.

Because of his suits at Pontarlier he found it advisable to leave France for a few months, which he spent at Neuchâtel, where he met the Genevese Liberals Clavière and Duroveray and where he published his *Des lettres de cachet et des prisons d'état*, the best known of his earlier writings. From September, 1783, to August, 1784, he was in Paris, where he seems to have begun his lifelong intimacy with Henriette van Haren, a young woman of 19, known as Madame de Nehra, whose influence over Mirabeau was exerted entirely for his good. In August, 1784, he withdrew to London to allow another storm to blow over. In England he met his old school-fellow, Sir Gilbert Elliot (later first Earl of Minto), Mr. (later Sir) Samuel Romilly, Lord Lansdowne, and other well-known men. He there wrote the *Considérations sur l'ordre de Cincinnati*, which caused a sensation in the United States. After nine months in England the intercessions of Madame de Nehra enabled him to return to Paris, where he entered into intimate relations with the Genevese exiles and other Liberals, like Brissot, and wrote numerous pamphlets on financial questions, published during 1785. These were followed (1787-89) by his attacks on stockjobbing and his criticisms on Necker's administration of the finances. In the meantime he had twice visited Prussia, once on a secret mission for the government. On his first visit (December, 1785, to May, 1786) he was received by Frederick the Great, whose death occurred during his second visit at Berlin (July, 1786, to January, 1787). In 1787 he failed in an attempt to secure the position of Secretary to the Assembly of Notables, and his attacks on Necker drove him to take refuge in Prussia. Returning from this third visit to Berlin, he published in 1788 his most famous work, *De la monarchie prussienne sous Frédéric le Grand* (8 vols. and atlas, London, 1788).

In October, 1788, Mirabeau once more was reconciled with his father, and in January, 1789, he arrived at Aix to participate in the elections to the States-General. In April, having been rejected by his own order, the nobility, he was elected by the Third Estate both of Aix and of Marseilles to the States-General, and he chose to represent the former city. He was in Paris in time to publish on May 2, 1789, the first number of his newspaper, which, after some changes of title, finally took the name of *Courrier de Provence*, and a few days later to be present at the opening of the States-General at Versailles. He never had a following upon whom he could depend in the States-General,

where his success was always a result of his ability to take advantage of temporary enthusiasm or excitement—by his fluent oratory and the power of his personality. The true greatness of Mirabeau was not revealed until the publication of his works, and especially his correspondence with La Marck, many years after his death. From the first Mirabeau saw that the royal and ministerial scheme of financial reform would be insufficient to cure the existing evils, but he thought that reforms could be successfully carried out only by a strong and moderate government. He was the most powerful supporter of the idea of a limited or constitutional monarchy. From the opening of the States-General until his death two years later Mirabeau was the most important figure in public life in France, and the story of his life is that of the Revolution in its earlier stages. He took part in the debates concerning the status of the members of the Third Estate, and his attitude as their spokesman at the royal session of June 23 marked him as the champion of the Third Estate in the struggle which ended in the reorganization of the States-General as the National Assembly. He protested vigorously against the attempt to overawe the Assembly by the mobilization of troops around Paris, but his father's death on July 13 prevented his participation in the stirring events of the following day when the Bastille was stormed and destroyed by the populace of Paris. The protracted debates on the rights of the individual, and the radical measures for the destruction of the old order taken by the Assembly on August 4, called forth his protests. Still he recognized the importance of the proposed Declaration of the Rights of Man and took an active part in framing it. One by one he brought forward his favorite constitutional measures and defended them with all his powers of logic, eloquence, and persuasion, only to see them voted down. Nevertheless, there was hardly an important law passed by the National Assembly which did not show the influence of Mirabeau's views. After the failure of his proposition to choose the royal ministers from the members of the National Assembly, on Nov. 7, 1789, Mirabeau strove earnestly to put his great abilities at the service of the King, whom he had attempted to advise as early as October 15. He tried to work with Lafayette and Necker, but everywhere he was viewed with suspicion, his advice was never followed, and his assistance was rejected entirely or accepted with ill grace. Finally in May, 1790, he abandoned his attempts to cooperate with Necker and Lafayette, and, through La Marck, entered into regular relations with the King and Queen, for whom he wrote his famous series of notes of advice. This change was marked in the Assembly by his speech in favor of the royal prerogative, especially in questions of peace and war, which directed suspicion towards him, and caused a temporary outburst of popular indignation against him. He was largely responsible for Necker's resignation in September, 1790, and for the appointment of Clavière in his place. In July he had been placed on the Diplomatic Committee of the Assembly and, in cooperation with his old friend Montmorin, the Minister of Foreign Affairs, had dealt with the perplexing questions of foreign relations, such as the annexation of Avignon and the maintenance of the Family Compact with Spain. He insisted that

no other country should interfere in the internal affairs of France; that other countries must keep their agreements with France; and that France must respect her agreements with other countries. On Nov. 30, 1790, he was elected president of the Society of the Friends of the Constitution, popularly known as the Jacobin Club, and on Jan. 29, 1791, he received the coveted honor of election as president of the National Assembly. His last note to the court, through La Marck, was sent on February 3. His last appearance in the Assembly was on March 27. On April 2, 1791, he died in the Rue de la Chaussée d'Antin in Paris. He was buried in the church of Ste. Geneviève (the Panthéon), but three years later his remains were removed to make room for those of Marat.

The greatness of Mirabeau has been generally recognized, but in estimating the details of his life and policy there has been the widest divergence of opinion. French republicans have condemned him unsparingly for his monarchical sympathies, but most of all because in return for his services the court paid his debts and supplied him with funds. In his defense it must be said that Mirabeau regarded himself as de facto prime minister, charged with the duty of saving France, a task to which he felt he alone was equal. The keynote of his advice to the court was that the King should transfer the court and the Assembly from Paris to Fontainebleau, or Compiègne, or some other small town of central France, where the influence of the mob of Paris would cease to control the Assembly and the King and the Assembly would be free to give France a strong monarchical constitution. Mirabeau had great power over men and made those who came under his fascination willing to merge their personalities in his and allow him to take all the credit for their labors. The *Souvenirs* of Etienne Dumont, one of his collaborators, first showed fully Mirabeau's methods of work and the way in which he made regular use of the services of Dumont, Reybaz, Pellenc, and even better-known persons like Clavière and the Abbé Lamourette. In Mirabeau everything was on a colossal scale; in personal appearance and moral character he was almost a monster; in intellect and powers of endurance he was a Titan. In his personality all that was noblest and best of the French Revolution seemed combined with the greatest of its characteristic evils. Some historians have mourned Mirabeau's death, because they believed that had he lived he would have saved France from the excesses of the Reign of Terror through his gift of practical statesmanship and his freedom from the doctrinaire vagaries that obsessed some of the later leaders of the Revolution.

Bibliography. Mirabeau, *Œuvres* (9 vols., Paris, 1825-27), is the most complete collection of his writings, but lacks the *Monarchie prussienne; Mémoires de Mirabeau écrits par lui-même, par son père, son oncle, et son fils adoptif* (9 vols., ib., 1834-35) is still the most important authority, in spite of many defects. Consult: P. F. Willert, *Mirabeau* (London, 1898); H. M. Stephens, *The French Revolution* (New York, 1902); Thomas Carlyle, *The French Revolution*, edited by J. H. Rose (3 vols., ib., 1902); H. E. von Holst, *The French Revolution Tested by Mirabeau's Career* (2 vols., Chicago, 1894); C. F. Warwick, *Mirabeau and the French Revolution* (Philadelphia, 1905). For Mira-

beau's relations with the court, consult *Correspondance entre le Comte de Mirabeau et le Comte de la Marck pendant les années 1789, 1790 et 1791* (Paris, 1851), and F. Schwartz, *Mirabeau und Marie Antoinette* (Berlin, 1891). For Mirabeau as an orator, see F. V. A. Aulard, *L'Éloquence parlementaire pendant la révolution française* (Paris, 1882); for his methods of work, E. Dumont, *Recollections of Mirabeau and of the Two First Legislative Assemblies of France* (Eng. trans., London, 1832), and Reybaz, *Un collaborateur de Mirabeau* (Paris, 1874); for his election to the States-General, G. Guibal, *Mirabeau et la Provence* (ib., 1887-91); for his career in the Assembly, Reynald, *Mirabeau et la Constituante* (ib., 1872); also G. Leloir, *Mirabeau à Pontarlier* (ib., 1886). Tallentyre, *Life of Mirabeau* (London, 1908); Louis Barthou, *Mirabeau*, translated from the French (ib., 1913), containing a bibliography. Of other biographies may be mentioned: Victor Hugo, *Étude sur Mirabeau* (Paris, 1834); Auguste Vermorel, *Mirabeau, sa vie, ses opinions et ses discours* (5 vols., ib., 1879-80); Jules Barni, *Mirabeau* (ib., 1882); A. J. E. Rousse, *Mirabeau* (ib., 1891); W. R. H. Trowbridge, *Mirabeau, the demi-god* (London, 1907). See also Etienne Charavay, in *La grande Encyclopédie* and Albert Sorel, in *Essais d'histoire et de critique* (Paris, 1883); Cabanis, *Journal de la maladie et de la mort de Mirabeau*, edited by H. Duhne (ib., 1890). For his father, Victor Riqueti Mirabeau (1715-1789), consult also, L. G. L. G. de Lavergne, *Les économistes français du 18me siècle* (Paris, 1870); August Oncken, *Der ältere Mirabeau* (Bern, 1886); H. Ripert, *Le marquis de Mirabeau* (Paris, 1901).

MIRABEAU, SIBYLLE GABRIELLE ANTOINETTE DE RIQUETI DE, COMTESSE DE MARTEL DE JANVILLE. See MARTEL DE JANVILLE, GABRIELLE, COUNTESS.

MIRACLE PLAY (OF., Fr. *miracle*, from Lat. *miraculum*, miracle, from *mirari*, to wonder, from *mirus*, wonderful; connected with Gk. *μειδάρ*, *meidan*, Skt. *smi*, to smile). Strictly, the second stage in the development of the modern drama under religious auspices, though it is sometimes confounded with the first, for which, and for a general account of this development, see MYSTERY. The distinction between the two, where it is made, is based on the fact that whereas the mysteries proper took their subjects from the Scripture narrative, centering about the life of Christ and the great mysteries of the Christian faith, the miracle plays were taken rather from the lives of the saints. The significant features of this change were that by getting away from the sacred text of the Scriptures greater latitude was gained and a greater range of characters; a nearer approach to a representation of contemporary life was thus also permitted, and a freer introduction of the comedy element than reverence would allow in the earlier form. Matthew Paris mentions a miracle play, *Ludus de Sancta Katharina*, that was performed at Dunstable about 1110, under the direction of a certain Geoffrey, afterward abbot of St. Albans. Again, William Fitz-Stephen, in his *Life of Thomas Becket* (about 1182), writes approvingly of London plays on

the miracles and sufferings of martyrs and confessors. Other miracle plays, based on the lives of St. Fabian, St. Sebastian, St. Botolph, St. George, and St. Crispin, were performed in the fourteenth, fifteenth, and sixteenth centuries. Very few texts of English miracle plays have been preserved; but from numerous continental specimens it may be inferred that they were in aim and structure similar to the mysteries. At the end of the nineteenth century and at the opening of the twentieth something like a revival of this dramatic form, or of this form blended with the mystery play, was attempted with some success in France, in England and Ireland, and in Germany, the efforts of Maeterlinck and Yeats being worthy of note. For bibliography, see MYSTERY.

MIRACLES (Lat. *miraculum*, wonder). An event or an effect in the physical world not explicable by known natural law and therefore assigned to a supernatural cause. Thus defined, an event which is a miracle in one age is not in another, when its natural causes have come to be understood. The conception of the direct action of the gods in certain events goes far back of the idea of natural law into the earliest history of the race. The unusual event was a wonder and challenged attention. It was naturally explained as the action of some invisible, superhuman power. The meaning of miracles still preserves the memory of this primitive conception. The next step was to regard this wonder as a sign of the presence or power of the divine being who caused it; so miracles came to be looked for especially at the shrines of the gods or on the occasion of sacrifices. The temple of Æsculapius in Greece was filled with the crutches and staffs of the lame who had been healed by the god, and religious story contains many tales of how the gods verified their presence at a sacrifice by some striking event. Aside from this, however, unexpected and startling occurrences might always be assigned to the gods. Certain classes of events which seemed to have no visible causes were quite uniformly assigned to the direct will of the gods—like thunder, which the Psalmist calls "the voice of God," and dreams, trances, and waking visions, when vivid and inexplicable. The Hebrew race shared with all the ancient world a ready belief in the abundant direct activity of God in the world. In fact, natural and supernatural is not the proper antithesis to use of ancient ideas, but rather usual and unusual, expected and unexpected. A worshiper might demand such a proof of the presence and approval of God as did Gideon in the matter of the fleece. (Judg. vi. 36-40.) The Old Testament represents, in its consideration of miracles as well as in other things, the primitive point of view. One may say that the conception of miracles, as understood by Christian theology, had not yet arisen. Dreams and their interpretation are believed to come from God, and even the life of the beasts is the direct gift of breath from God. (Ps. civ. 29, 30.) At the same time, unusual events are taken as signs from God and as verification of the words of his prophets. (1 Sam. xii. 16-18.) In this evidential use of the unusual in nature lies the beginning of the later Christian conception of a miracle as an event not explicable by natural law and having a religious purpose. The New Testament expresses various ideas of the significance of such events in its various terms for them—wonders, powers, signs, works;

but the chief value of miracles to the writers of the New Testament lies in their use as evidence of the presence and power of God. Though Christ himself never based the authority of his teachings on the evidence of miracles, yet it is plain that the feeling both of the populace and of the early Church is expressed by the saying of Nicodemus: "We know that thou art a teacher come from God; for no man can do these signs which thou doest except God be with him." (John iii. 2.) The apostolic church also believed that miraculous events occurred among them and were tokens of the working of the spirit of God. (Acts xi. 15-18; 1 Cor. xii. 4-11.) Even in the subapostolic church the divine power was held to be manifested, especially in the name of Jesus. (Heitmüller, *Im Namen Jesus*, Göttingen, 1903.) Clement of Rome, Irenæus, Origen, Athanasius, Augustine, and Jerome all bear witness to the belief in contemporaneous miracles. So far the belief in miracles created no particular problem, but was a natural inference from the belief in any supernatural power actively interested in the affairs of the world.

The problem of miracles arose in Christian theology in the time of the schoolmen with the sharp demarcation between the natural and the supernatural. A philosophical conception of miracle arose as that which is apart from nature. The popular interpretation was an event contrary to nature, and the popular inference was that the more opposed to nature a miracle might be, the more it was evidence of the supernatural. These ideas passed into Protestantism and have colored much of the use of miracles as Christian evidence. The Church of the Middle Ages held that miracles still took place, though some of the schoolmen, as Abelard, freely criticized accounts of particular miracles. This belief in the continuance of the power of miracle has continued in the Roman Catholic church, which has always held evidence of miraculous power to be a prerequisite to the canonization of a saint. The Protestant church has usually rejected postbiblical miracles, regarding the function of miracle to be the attestation of the divine truth of the special revelation of God in the biblical periods.

In the history of the discussion, different definitions of miracle have been given.

1. That it is a violation of a law of nature by a volition of the Deity. This is the definition which Hume used. Hume's famous argument against miracles is that all knowledge rests upon experience; but experience confirms the order of nature, and miracles are so contrary to all experience that it is more reasonable to disbelieve any testimony about them than to believe a miracle. John Stuart Mill, *Essays on Theism*, asserts that, if a miracle could happen, it would be impossible to prove it. The common answer to this position has been that the possibility of events is not limited to usual past experience, and therefore that it is impossible to prove that miracles cannot take place. Spinoza held that "nothing happens in nature which is in contradiction to its universal laws," and, since miracles are contradictions to law, they are impossible. This has been met by saying that miracles are contrary to nature only if nature is taken as a mechanism.

2. The definition of a miracle as contrary to nature is neither biblical nor in accord with the best theological thinking. Augustine held that

miracles are not against nature, but only against nature as we know it. Miracles have been defined as events not explained by the known laws of nature. It is in accordance with this that various fields, once considered miraculous, have been removed from the field of miracle by the fuller understanding of natural law—dreams, the thunder, eclipses, trances and visions, many kinds of healings. This definition admits the reality of the biblical miracles and says that, if we knew the laws of nature better, we should doubtless find explanation for them all. This position is sometimes taken from a religious point of view, conceiving that an all-wise God, in constructing the universe, must have so arranged things that all events which happen fall into their place as parts of an ordered and harmonious whole.

3. An element of religious purpose has nearly always entered into the Christian definition of miracles. A mere wonder is not a miracle. It must have a religious significance. If, to use Arnold's illustration, the pen should turn into the penwiper, it would be a very strange event, but its religious significance is not obvious, and it would not be a miracle. On the other hand, if the crossing of the Red Sea were effected by means of a wind, at the will of God, for a religious purpose, it would still be a miracle. Whenever God so orders affairs that an extraordinary event fulfills a religious purpose in life, that event may be called miraculous, even if its immediate cause is the operation of natural law.

4. A definition of miracle is sometimes given which extends it beyond the biblical miracles, or those in ecclesiastical history, to all direct spiritual action of God. Miracle is God's direct action in the world of matter or of mind. On this basis it is held that the Christian religion is miraculous, not merely because of events in Christ's life, but because it is the field of the direct action of God. Conversion, the life of prayer, the communion of God with man, the grace which enables man to combat sin, are all miraculous. It is certainly true that the historic doctrines of grace and redemption make Christianity an essentially miraculous religion.

In the modern world there have been two stages of the discussion of miracles: one under the influence of the growing sense of a natural order, which produced the objections to miracles raised by the English deists, Hume, and the French and German rationalists; the other under the influence of the modern scientific conception of the uniformity of law, expressed by the doctrine of evolution and the historical study of religion. The older objections of Hume and his contemporaries are no longer of importance. The conceptions upon which both these objections and the answers rest have been displaced by modern science. The insight into the inexhaustible complexity of nature has made men more modest in asserting what may or may not be possible, or to be sure that all the causes of any event have come into view. At the same time the sense of an ordered universe has become stronger, and the older idea of a miracle as the action of God thrusting His hand into the moving machinery of His world seems to debase the conception of God. A growing spiritual sense has also led to the emphasis on the moral and religious as evidence of the revelation and power of God. The value of miracles as evidences of the divine character of the biblical revelation because they were events

only explicable by the power of God has been very much diminished. Miracles merely as acts of power have no religious significance. They are external; modern religion demands evidences within the personal experience. The result is that, while 100 years ago miracles were considered one of the great proofs of the Christian religion, they are to-day rather burdens than helps. Theology holds the possibility of miracles; for the most part it holds that some at least of the biblical miracles happened; it holds that they were evidences for religion at the time they occurred, but that they belong to the lower grade of evidences, and that the moral and spiritual proofs of religion are higher and more valuable.

But to assert that miracles may happen is not to claim that they did happen. The critical study of the Bible has introduced a new problem: how far are the narratives of miracle in the Bible to be taken as statements of fact? Certain classes of miracles will be set aside: those in books held to be fiction; those in apocalyptic literature, where miraculous visions are a part of the literary form; those told in legendary folk tales; and those where a miraculous cause is assigned for what we now see may have been a natural event. The principles of criticism must be allowed the same play in the New Testament as in the Old, but the nearly contemporaneous character of the writing of the New Testament and the abundant evidence they contain of belief in a large body of miraculous healings forbid the treatment of them as wholly legend. Many who are critical of the Old Testament narratives and of certain accounts in the New yet hold that Christ had a unique power which manifested itself naturally in miracles of benevolence, like healings and even raising from the dead. To such persons Christ himself is the great miracle, and his miracles are not mere wonders, but manifestations of his own character. The present tendency, however, is to remove attention from the miracles and centre it upon Christ's character. Historical criticism even claims the right to question, and if necessary to reject, the narratives of Christ's miraculous birth and resurrection without disloyalty to the essential principles of his religion; a claim, however, which is not always acknowledged by conservative theology. Christian thought is not entirely at one regarding the place of miracles in Christian belief. Some hold that the belief in miracle is a necessary and fundamental part of Christian doctrine; others that it is unessential, that it belongs to the interpretation of nature rather than to the realm of spiritual truth, and that Christian belief does not require the acceptance of miracles as the term is understood in historic theology.

MIRACLE WORKER. See GREGORY THAUMATURGUS.

MIRA DE AMESCUA, mē'rā dā à-mās'kwā, ANTONIO (?1578-1644). A Spanish dramatist. Born at Guadix, he took orders, obtained a canonry in his native town, and settled in Madrid early in the seventeenth century. In 1610 he had become archdean of Guadix. He accompanied the Count of Lemos to Naples, and on his return in 1619 was appointed chaplain to the Cardinal Prince Ferdinand of Austria. He early attained distinction as a dramatist, for he is mentioned as such by Rojas Villandrando in his *Loa* (Madrid, 1604), which was written late in 1602 or early in 1603. Mira de Amescua's plays are few, but of even execution, a combination not often found among Spanish writers and one which invites comparison with Alarcón. They were influential at home and abroad. The lack of a good edition of Mira's complete works is responsible for his not being better known to-day.

Bibliography. *Biblioteca de autores españoles*, vol. xliii (2d ed., Madrid, 1875), contains *poetas*; id., vol. xlv (2d ed., ib., 1881), contains five *comedias*; H. A. Rennert, "Mira de Mescua et La Judia de Toledo," in *Revue Hispanique*, vol. vii (Paris, 1900); *Comedia famosa del Esclavo del Demonio*, edited by M. A. Buchanan (Baltimore, 1905); Cristóbal Pérez Pastor, *Bibliografía Madrileña*, part iii (Madrid, 1907); T. G. Ahrens, *Zur Charakteristik des spanischen Dramas im Anfang des XVII. Jahrhunderts* (Halle, 1911).

MIRAFLORES, mē'rā-flō'rās, MANUEL PANDO FERNÁNDEZ DE PINEDO MACEA Y DÁVILA, MARQUIS OF (1792-1872). A Spanish statesman and historian, holding also the title of Count of Villapaterna. He was born at Madrid, was sent as Ambassador to London in 1834, and was Ambassador at Paris in 1838-40. In 1846 he was Premier and in 1863 again filled the same office. He was Ambassador to Vienna in 1860 and was several times President of the Senate. He wrote

a number of works which are of value for the political history of Spain in the nineteenth century. The most important is the *Memorias para escribir la historia de los siete primeros años del reinado de doña Isabel II* (1843). In addition to many of the most highly esteemed of the Spanish decorations for distinguished service he was Grand Officer of the French Legion of Honor. He was also elected a member of the Royal Academy of History at Madrid.

MIRAGE, mī-rāzh' (Fr., from *mīrer*, to gaze). A phenomenon extremely common in certain localities and due to conditions existing in the atmosphere. As a result of a deviation of the rays of light caused by refraction and reflection, objects seen with the eye appear in unusual positions and often multiple or inverted. One cause of mirage, such as occurs in a desert, is a diminution of the density of the air near the surface of the earth, often produced by the radiation of heat from the earth, the denser stratum being thus placed above instead of, as is usually the case, below the rarer. Now, rays of light from a distant object, situated in the denser medium (i.e., a little above the earth's level), coming in a direction nearly parallel to the earth's surface, meet the rarer medium at a very obtuse angle, and (see LIGHT) instead of passing into it they are reflected back to the dense medium, the common surface of the two media acting as a mirror. The image produced by the reflected rays will appear inverted and below the real object, just as an image reflected in water appears when observed from a distance. If the object is a cloud or portion of sky, it will appear by the reflected rays as lying on the surface of the earth and bearing a strong resemblance to a sheet of water; also, as the reflecting surface is irregular and constantly varies its position, owing to the constant communication of heat to the upper stratum, the reflected image will be constantly varying and will present the appearance of a water surface ruffled by the wind. This form of mirage is of common occurrence in the arid deserts of Lower Egypt, Persia, Turkestan, etc. In the case of mirage at sea the denser layers of air are next to the surface of the water, and the reflection takes place from the rarer atmosphere above. Consequently we have the object appearing in the air suspended and inverted. Sometimes images of objects are seen not above one another, but side by side, caused by the existence of bodies of air of different densities in proximity.

In particular states of the atmosphere reflection of a portion only of the rays takes place at the surface of the dense medium, and thus double images are formed, one by reflection and the other by refraction—the first inverted and the second erect. The phenomena of mirage are frequently much more strange and complicated, the images being often much distorted and magnified and in some instances occurring at a considerable distance from the object, as in the case of a tower or church seen over the sea or a vessel over dry land, etc. The particular form of mirage known as looming is very frequently observed at sea and consists in an excessive apparent elevation of the object. Consult Müller, *Lehrbuch der kosmischen Physik* (Brunswick, 1896).

MIRAMAR, mē'rā-mār'. An Imperial palace and public pleasure resort on the Gulf of Triest, 6 miles northwest of Triest (q.v.).

MIRAMICHI (mīr'ā-mé-ahé') RIVER. The

second largest river in New Brunswick, Canada. It is formed by the junction of the northwest and southwest Miramichi (Map: New Brunswick, C 2). It flows, after a course of about 100 miles, into the Bay of Miramichi, a part of the Gulf of St. Lawrence. Pine woods abounding with game line the banks of the river, which is navigable for vessels of modern size for a distance of 40 miles from its mouth. The fishing is excellent, salmon and trout abound, and there is a state fish-breeding establishment on one of the tributaries.

MIRAMÓN, mē'rā-mōn', MIGUEL (1832-67). A Mexican general, of French descent, born in the city of Mexico. He was educated for the army and fought against the United States at Molino del Rey and Chapultepec. He saw much active service during the fifties and was promoted to be a lieutenant colonel in 1855. He was one of the leaders of the opposition to Comonfort (q.v.) in 1856 and supported Zuloaga, the representative of the clerical and reactionary party, in the movement which forced Comonfort to retire to the United States in 1858. Later in the same year he was chosen acting President by a *Junta de Notables*, but, contrary to the expectations of the junta apparently, he turned the office over to Zuloaga and assumed the conduct of the campaign against the Liberals, led by Juárez. Returning to the capital, he was again installed as acting President, exercising its duties until December, 1860, when his defeat by Juárez at Calpulalpam forced him to leave the country. He spent some time in Europe and advocated foreign interference in Mexican affairs. He reappeared in Mexico in 1866, after the announcement that the French army was to leave the country, and offered his services to Maximilian. Raising an army in the West, he joined the Emperor at Querétaro, where he was wounded during the final struggle with the republican forces. He was tried and condemned to be shot with the Emperor on June 19, 1867. As they were lined up for the execution, Maximilian insisted that Miramón should take the place of honor in the centre, as a tribute to his bravery.

MIRANDA, mē-rān'dā. A Portuguese poet. See *SÁ DE MIRANDA*, FRANCISCO DE.

MIRANDA, mī-rān'dā. In Shakespeare's *Tempest*, Prospero's daughter and the ladylove of Ferdinand.

MIRANDA, mē-rān'dā, FRANCISCO (?1756-1816). (Miranda's own statements would indicate that he was born in 1752; his lawyer Chauveau Lagarde asserts the date was 1754; a baptismal certificate published by Blanco bears the date 1756.) A Spanish-American revolutionist, who was born in Venezuela and entered the Spanish army, rising to the rank of captain. He resigned in order to serve with the French in the United States. He was then sent to Cuba, where he engaged in illegal trade and was obliged to take refuge in Europe. The French Revolution called forth his enthusiastic admiration. He served in the French Republican army and gained the rank of major general. The defeat at Neerwinden (1793) was attributed largely to his treachery, and the suspicion led to his arraignment before the Revolutionary Tribunal, which unanimously acquitted him. Later in the same year he was again arrested and placed in prison, where he was kept without trial for a year and a half. After the fall of the Girondists he fled to England and endeavored in vain to

induce William Pitt to aid him in an attempt to free Venezuela from the Spanish dominion. In 1803 he went to New York, where he found means to fit out two vessels and some 200 volunteers, with whom he sailed for South America in 1806. The great popular demonstration in his favor which he had expected was entirely lacking. In 1810 he organized another expedition and took possession of Valencia, Puerto Cabello, and nearly the whole of New Granada. Miranda organized a revolutionary government, proclaimed a constitution, made himself Vice President, and entered Carácas in triumph in April, 1812. The members of the government were not able to act in harmony. Miranda was taken prisoner by the opposition faction of revolutionists in July and shortly afterward fell into the hands of the Spanish authorities, by whom he was sent to Spain. He died in the dungeons of the Inquisition at Cadiz three years later. Consult: Biggs, *History of Miranda's Attempt in South America* (London, 1809); Marqués de Rojas, *El General Miranda* (Paris, 1884); id., *Miranda dans la révolution française* (Carácas, 1889); the Spanish edition of this latter work (ib., 1889) contains a few additional source materials; also W. S. Robertson, *Francisco de Miranda and the Revolutionizing of Spanish America* (Washington, 1909).

MIRANDOLA, mē-rān'dô-lā. A town in the Province of Modena, Italy, 19 miles north-northeast of the city of Modena (Map: Italy, C 2). The little town is regularly laid out. The old Ducal Palace of the Pico family, the cathedral, and the church of Gesù are the most important buildings. It has a gymnasium, a technical school, and a library. The principal industries are cattle raising and the production of silk and rice. Pop. (commune), 1901, 13,731; 1911, 16,740.

MIRANDOLA, GIOVANNI PICO DELLA. An Italian humanist. See PICO DELLA MIRANDOLA.

MIRANHA, mī-rā'nyā. See MARANHA.

MIRAT, mē'rūt. See MEERUT.

MIRAVAL, mē'rā'vāl', RAIMON DE (c.1190-1216). A Provençal poet. His poverty compelled him to subsist on the favor of the great lords at whose courts he seems to have passed most of his time. His chief patron was Raimon VI of Toulouse, addressed in his poems by the name Audiart. Consult Andraud, *La vie et l'œuvre du troubadour Raimon de Miraval* (Paris, 1902).

MIRBACH, mēr'bāg, JULIUS, COUNT VON (1839-). A German politician, born in Sorquitten, East Prussia. He studied law at Königsberg, Bonn, and Berlin and served as officer in the German army, resigning in 1865. In 1874 he entered the Prussian House of Lords and in 1878-81 and 1886-98 was a member of the Reichstag and a prominent figure in the German Conservative party, taking a foremost part in economic and agrarian reforms, acting as leader of the *Steuer-und Wirtschaftsreformer* (1879 et seq.). He was created Count in 1888.

MIRBEAU, mēr'bō', OCTAVE (1850-1917). A French novelist and playwright, born at Trevières (Calvados). After a stormy journalistic career he published his first novel, *Jean Marcelin*, in 1885, but gained note with *Lettres de la chaumière* (1886), a tale of his native Normandy. There followed *Le Calvaire* (1886); *L'Abbé Jules* (1888; in Russian, 1912); *Sébastien Roch* (1890); *Le jardin des supplices* (1890); the exceedingly unsavory and very

popular *Les mémoires d'une femme de chambre* (1901; in English, *Experiences of a Lady's Maid*, 1911); *Les vingt-et-un jours d'un neurasthénique* (1902); *Le jardin des supplices* (1902); *Dans l'antichambre* (1905). He was successful on the stage with *Les mauvais bergers* (1807), and still more with *Les affaires sont les affaires* (1903), produced with great success in New York in 1905 as *Business is Business*. A number of one-act plays are contained in *Farces et moralités* (1904). In 1909 he wrote *Le foyer*, which was suppressed by the censor, and in 1913 *Dingo*.

MIRBEL, mēr'bēl', CHARLES FRANÇOIS BRISSEAU DE (1776-1854). A French botanist, born in Paris. In 1800 he began a botanical course at the Athénée and in 1803 he was made intendant of the Malmaison Gardens. In 1806 he was made a councillor of state at the Dutch court of Louis Bonaparte, and as director of fine arts he was charged with the mission of organizing a school in Paris for Dutch artists. In 1808 he became a member of the Institute. He was professor of culture at the Botanical Garden (1828) and at the Museum of Natural History (1829). His great contributions to structural botany are recorded in his works: *Traité d'anatomie et de physiologie végétale* (1802); *Exposition de la théorie de l'organisation végétale* (1809); *Éléments de botanique et de physiologie végétale* (1815); *Histoire naturelle des végétaux classés par familles* (18 vols., 1802-26).

MIRBT, mērt, CARL THEODOR (1860-). A German Church historian, born at Gnadenfrei in Silesia. He was educated at the universities of Halle, Erlangen, and Göttingen; was docent at Göttingen for a year; and then was professor of ecclesiastical history at Marburg from 1889 to 1912, when he went back to Göttingen. His published work, which deals with the Roman Catholic church and with the history of Protestant missions, comprises: *Die Wahl Gregors VII.* (1892); *Die Publizistik im Zeitalter Gregors VII.* (1894); *Der deutsche Protestantismus und die Heidenmission im 19. Jahrhundert* (1896); *Quellen zur Geschichte des Papsttums und des römischen Katholizismus* (1895; 3d ed., 1910); *Ultramontanismus im 19. Jahrhundert* (3d ed., 1903); *Mission und Kolonialpolitik in dem deutschen Schutzgebieten* (1910); *Die Frau und die deutsche Kolonialmission* (1912); *Geschichte der katholischen Kirche von der Mitte des 18. Jahrhundert bis zum Vatikanischen Konzil* (1913).

MIRÉS, mē-rá', JULES (1809-71). A French financier and speculator. He was born at Bordeaux. In company with Moïse Millaud he began to buy up the press of Paris; he purchased the *Chemins de Fer* and afterward the *Constitutionnel* and *Le Pays*. He published independently the *Conseiller du Peuple*. Swaying public opinion in this manner, he organized the *caisse générale des chemins de fer*, or railway bank, began to build railroads in Spain and elsewhere, negotiated municipal and national loans, and acquired an immense fortune. During the last four years of his career his speculations amounted to 1,500,000,000 francs. Arrested for fraud in 1861 he was condemned to imprisonment, but was acquitted in 1862 after an appeal. He resumed banking operations, but people came to distrust his promises of magnificent possibilities. He was a man of infinite resources, quick to plan, daring to act,

carrying out his immense coups by gigantic combinations, overcoming all opposition by the plentiful use of money and with the help of his hired journalists and politicians. He published in 1870 *Un crime judiciaire*, and carried on a lively war of pamphlets with his enemies.

MIRFIELD, mēr'fēld. A manufacturing town and urban district in the West Riding of Yorkshire, England, 5 miles northeast of Huddersfield, on the Calder, one of the chief railway centres in the country. It has manufactures of woolen and cotton goods, carpets, and blankets. There are coal mines near by. Pop., 1901, 11,341; 1911, 11,712.

MIRIAM. The sister of Moses and Aaron. She is called a "prophetess" and is represented as celebrating the deliverance of the people from Egypt as the leader of a female choir (Ex. xv). Apart from this, she is mentioned again only in connection with Aaron's rebellion against Moses, in which Miriam stands on Aaron's side. She is smitten with leprosy as a punishment (Num. xii), but after seven days' isolation (Lev. xiii. 5) is healed by Yahwe at Moses' solicitation. Her death takes place at Kadesh (Num. xx. 1). Miriam, though not expressly named, is thought to be the sister referred to in the story of Moses' infancy (Ex. ii), who acts as a nurse and protector to him. The name may be connected with Merari, one of the sons of Levi (Ex. vi. 16). It has been suggested that Aaron and Miriam represent priestly families vying with that of Moses, that the latter prevailed, but that a compromise was effected, showing itself in the later tradition. The association between Moses, Aaron, and Miriam once established is supposed to have given rise to further elaboration which was adjusted to the general priestly narrative in the Pentateuch. The allusion in Micah vi. 4 to "Moses, Aaron, and Miriam" as the forerunners in the redemption of Israel is thought by some scholars to be a valuable indication of the period at which the combination of the three in popular tradition and legend had taken place.

MIRIBEL, mē'rē'bēl', MARIE FRANÇOIS JOSEPH DE (1831-93). A French general. He was born at Montbonnot, studied at the Ecole Polytechnique and at the Military Academy of Metz, and in 1853 was commissioned a lieutenant of artillery and sent to the Crimea. He fought in Italy in 1859 and in Mexico (1862-65); served on the international commission dealing with the use of explosive bullets; and in 1868 was appointed military attaché in St. Petersburg. Miribel fought bravely at Champigny and Buzenval in the Franco-Prussian War; commanded a corps of artillery against the Commune; and from 1877 to 1879 was chief of the general staff. His reappointment by Gambetta to this post in 1881 created great excitement, and he resigned after the fall of Gambetta's ministry. In 1888 he was commanding general of the Sixth Army Corps. In 1890 he was once more made chief of staff with greater powers than before, and showed himself an able administrator.

MIRIM, mē-rēm'. A lake or lagoon in the extreme south of Brazil, on the boundary of Uruguay (Map: America, South, D 6). It is 130 miles long and from 5 to 25 miles wide, and is separated from the Atlantic Ocean by a low sandy tract from 15 to 40 miles wide, containing several true coast lagoons. It receives a number of small rivers from the west, and,

though its shores are low and marshy, it is not in direct communication with the ocean, but discharges its waters northward into the Lagoa dos Patos (q.v.). Like the latter, it was evidently formed through the cutting off by sand bars of a large bay of the ocean. The water of Lake Mirim is fresh, and there is no rise or fall of the tides in it.

MIRITI (mê-rê'té) **PALM.** See MAURITIA.
MIRKHOND, mēr-kōnd', HAMAN ED DIN (1433-98). A distinguished Persian historian, born of Sayyid descent from a Bokharan family probably near Nishapur. About 1474, under the patronage of Mir Alishir, Mirkhond began his historical work, entitled *Rauzat-us-safā* (Garden of Purity). It is of great value and, on the whole, is a very remarkable compilation, being, save for the seventh volume, which deals with the latter part of the fifteenth century and must have been by Mirkhond's son, Khondamir (1475-1535), the work of a single man. Beginning with mythical times, the *Garden* contains biographical notices of the leading Persian notables down to 1523. The part on the early kings was translated by Shea (London, 1832); that on the Sassanids, into French by S. de Sacy (Paris, 1793) and Jaubert (ib., 1843); on the Samanids, into Latin by Wilken (Berlin, 1808) and into French by Defrémery (Paris, 1845); on the Seljuks, by Vullers into German (Giessen, 1837); and the story of Mohammed by Rehataek into English (5 vols., London, 1891-94) and from English into French by Lamaisse (Paris, 1894).

MIRMILLO'NES. The name given by the Romans to a kind of gladiator (q.v.).

MIR'ROE (OF. *mirroer*, *mirour*, Fr. *miroir*, It. *miratore*, *miradore*, from Lat. *mirari*, to look, from *mirus*, wonderful; connected with Gk. *μειδᾶν*, *meidan*, Skt. *smi*, to smile). An object having a smooth or polished reflecting surface by which virtual or real images of an object are produced, and the direction of light or heat waves changed according to the laws of reflection. Mirrors are used largely for toilet and decorative purposes, and also in scientific apparatus and in numerous other practical devices to concentrate, scatter, or divert rays of light or heat, as in practical illumination. The action of the mirror depends on the law of reflection where it is stated that the angle of reflection must equal the angle of incidence and be in the same plane. This optical principle was well known to the ancients and was doubtless long preceded by an actual practical knowledge of the instrument. Probably for ages after the civilization of man commenced the still waters of ponds and lakes were the only mirrors. We read in the Pentateuch of mirrors of brass being used by the Hebrews, while it is known that mirrors of bronze were in very common use among the ancient Egyptians, Greeks, and Romans, and many specimens are preserved in museums. Praxiteles taught the use of polished silver for mirrors in the year 328 B.C. and polished mirrors of obsidian or natural glass were used by the Romans.

Mirrors of glass were first made at Venice in 1300; and judging from those still in existence they were very rude contrivances compared with those of modern make.

It was not until 1673 that the making of mirrors was introduced into England, and the industry has since developed in Europe and America to a point where it is a very important

manufacture; and mirrors can be produced of any size to which plate glass can be cast.

For many centuries mirrors were made according to the process originally introduced at Venice—by backing a sheet of glass with an amalgam of mercury and tin. The surface was overlaid with sheets of tin foil, rubbed down smooth, and the whole covered with quicksilver, which immediately formed an amalgam with the tin. The superfluous mercury was then run off and a woollen cloth held firmly over the surface by means of iron weights. After this pressure had been continued 24 hours, more or less, the weights and cloth were removed and the glass placed on a table with a movable top, which was gradually inclined until the unamalgamated quicksilver had entirely drained away and only the surface of perfect amalgam remained adhering to the glass. This process, which was long used, was open to many objections, not least of which was its extreme unhealthfulness for the workmen. The process was also long and tedious, and at best made an unsatisfactory mirror, reflecting less than half the rays of light.

The first attempt to back the glass with silver was made by Liebig in 1836, and different solutions were proposed by other chemists, all of which produced mirrors that were satisfactory for a short time but finally became spotted. In 1855 Pettijean patented a process which, with various modifications, is the one now in general use. The method of mirror manufacture common in America may be described as follows: The raw stock or plain plate glass reaches the factory carefully packed in cases of immense size. The glass is first thoroughly inspected and all defects marked. It then goes to the cutters' department, where it is cut into the proper sizes. Thence it is moved to the beveling department, where it is beveled and polished on rapidly revolving emery wheels of varying degrees of smoothness, the plates—some of them of enormous size—being lightly held against the wheel by the workmen. After both surfaces, including the beveled edge, have been reduced, as nearly as possible, to a condition of perfect smoothness, the glass is passed on to the silvering department. Here it must be thoroughly cleansed, and so delicate is this operation that a specially distilled water is often required for the purpose. The glass is now ready for the essential process of silvering. The nitrate of silver is dissolved in water, to which ammonia is then added, and is precipitated by a solution of Rochelle salts or tartaric acid. The glass is placed on warm tables and the solution poured over it. The heat helps the silver to precipitate and adhere to the glass. The silver back receives a coat of shellac and then of paint or of asphaltum varnish containing white lead, which completes the process. Silvered mirrors reflect from 20 to 25 per cent more of light than those backed with quicksilver.

The optical considerations involved in reflection will be found fully discussed together in the article on LIGHT, but brief mention may here be made of mirrors whose reflecting surfaces are other than plane. In a concave spherical mirror we have distant rays of light or heat brought to a focus and a real image formed. Conversely, if a point source of light is placed at the focus of the mirror, a parallel beam of light results. The first idea is made use of in the reflecting telescope (see TELESCOPE), while the

latter is employed in the searchlight (q.v.), recent types of which have been made with a gold reflecting surface.

A *parabolic mirror* is one "in which every section through the principal axis cuts the surface in a parabola, so that rays from a light placed at the focus are all reflected parallel to the axis and, conversely, parallel rays are brought to the focus." The reflector of a locomotive headlight is thus constructed. See **ABERRATION, SPHERICAL; LIGHT.**

Cylindrical mirrors do not play as important a part in optics and optical instruments as those of spherical and parabolic cross section, but their effects are sometimes interesting. By using a glass that is curved instead of flat the reflected shape of the object will become distorted, a *concave* cylindrical mirror lengthening it at the expense of width and a *convex* mirror producing the opposite effect.

As heat is reflected as well as light from the surface of a mirror, a concave mirror may be used to bring rays of light to a focus. In this way combustible substances may be set on fire at a distance from the reflector whence they receive their heat. The *Archimedean mirror* was made on this plan. A series of mirrors set in a concave curve concentrated the rays of light upon an enemy's ship, causing it, according to the story, to burn.

MIRROB CARP. An artificial variety of carp (q.v.) with very large scales in two or three rows along the sides of its body, which is otherwise bare.

MIRROR FOR MAGISTRATES, A. A long series of poems on incidents in English history showing the tragedies in the lives of great men. The plan was suggested by Boccaccio's *Falls of Illustrious Men* and Lydgate's *Falls of Princes*, and was devised by William Baldwin, George Ferrers, and Sackville, who wrote a general introduction called the "Induction." It was partly printed in 1555, when it was stopped by Lord Chancellor Gardiner. It was licensed, however, in 1559, and then contained 19 metrical biographies, beginning with Tressillian in Richard II's reign. New editions, with additional lives by various writers, appeared in 1563, 1574, 1578, 1587, and 1610, and a reprint of the whole by Haslewood in 1815. Some of the best-known contributors are Michael Drayton, Thomas Churchyard, John Skelton, and Thomas Sackville, whose "Induction" and "Complaint of Stafford, Duke of Buckingham," are the most valuable parts of the work.

MIRROR OF KNIGHTHOOD, THE. A translation of a Spanish romance, *Cavallero del Febo* (The Knight of the Sun), which tells the adventures of Febo and his brother Rosclair. It belongs in a sense to the Amadis cycle of romance, as the father of the Knight of the Sun was related to Amadis. The Spanish version was evidently the work of several and was left unfinished. The translation of the romance into English was printed in 1578. See *Dunlap's History of Prose Fiction.*

MIRTOV. See *LAVROV, P. L.*

MIRYACHIT, mēr-yā'chit. An Oriental nervous affection, the chief peculiarity of which is mimicry. The patient imitates words and actions said or done by his immediate neighbor. In Java the disease is called *lata*. The jumpers of Canada and Wales are thought to be afflicted with a similar disease. See **JUMPERS.**

MIRZA, mēr'zā (Pers. *mirzā*, contracted from

Amīr Zādā, son of the prince). A Persian title. As a prefix preceding the surname of the individual it is a common Persian title of honor, but when annexed to the surname it designates a prince or a male of the blood royal.

MIRZAPUR, mēr'zā-pūr'. The capital of a district of Benares, in the United Provinces, British India, on the right bank of the Ganges, 30 miles southwest of Benares (Map: India, D 4). It is a well-built city, the river front is lined with a series of fine landing places, and there are many mosques, temples, and residences of rich European merchants. It is noted for its manufactures of carpets and rugs and has large brass and shellac factories. Prior to the opening of the railway to Allahabad it was the largest cotton and grain trading centre on the Ganges and the converging market of north and Central India. Pop., 1901, 66,071; 1911, 32,332.

MIRZA SCHAFFY, mīr'tā' shāf'ē. See *BODENSTEDT, FRIEDRICH MARTIN VON.*

MISANTHROPE, mē'zān'trōp', Lx. A comedy by Molière (1666) based on a study of character rather than on incidents. It is considered Molière's masterpiece and shows his style at its highest development.

MISCARRIAGE. In the broadest sense, a breach of legal duty. This is the signification of the term as employed in the fourth section of the English Statute of Frauds and in similar statutory provisions in the United States, which, in order to make a person liable to answer for the debt, default, or miscarriage of another person, require a special promise in writing.

In medical jurisprudence the term "miscarriage" is sometimes employed as the equivalent of abortion as denoting the premature expulsion of the fetus before it becomes capable of an independent life. The act of causing miscarriage or abortion in a pregnant woman except for the purpose of preserving her life is a crime at common law and by modern statutes. See **ABORTION.**

MISCEGENATION, mī's'jē-nā'shūn (from Lat. *miscere*, to mix + *genus*, race). Mixing of races; usually restricted to amalgamation of Caucasian and African races in America. The expression came into common use in discussions of negro slavery in the United States towards and after the middle of the nineteenth century, when certain publicists advocated the gradual absorption of the blacks by intermarriage with whites. The expression is seldom employed in scientific discussion of racial problems, such collocations as mixing of races, blood blending, etc., taking its place. The process so denoted is of much importance—indeed, one of the primary factors of human development, as is shown by the fact that the most advanced peoples are those whose blood is most mixed. The process of racial assimilation is going on in every part of the world and with progressively increasing rapidity. Even in the United States, despite the most strenuous opposition on both national and sentimental grounds, the admixture of whites and blacks has gone so far that among the 9,000,000 enumerated as colored in the census of 1900, the population of pure-blooded Africans is comparatively small, while the admixture of red and white races has affected a proportion of the population which may be estimated at 30 to 60 per cent of the element reckoned as Indian. The data are too meagre to indicate the vital value of the mestizo type in the United States,

though the experience of Mexico suggests that the value is high. The more general aspects of racial blending are discussed under **MIXED RACES**. Consult C. B. Davenport, *Heredity of Skin Color in Negro-White Crosses*, Carnegie Institution (Washington, 1913). See **CROSS BREEDING IN MAN**.

MISCHIANZA, mĭs'kĕ-ān'tsā, THE. An elaborate fête or entertainment given at Philadelphia, May 18, 1778, during the Revolutionary War, by officers of the British army, in honor of Sir William Howe, who, having been superseded in the command of the British army in America by Sir Henry Clinton, was about to sail for England. The entertainment, which was given at Walnut Grove, the country seat of Thomas Wharton, lasted 12 hours and comprised a regatta, a mock tournament between the Knights of the Blended Rose and the Knights of the Burning Mountain, a dance, and a dinner. Captain (later Major) André was prominent in planning and directing the entertainment and wrote a detailed description, which may be found in Winthrop Sargent, *Life of Major André* (New York, 1902). Consult also J. F. Watson, *Annals of Philadelphia* (Philadelphia, 1856).

MISCHIEF, MALICIOUS. See **MALICIOUS MISCHIEF**.

MISDEMEAN'OR (from *mis-* + *demeanor*, from *demean*, from OF. *demener*, *deminer*, to manage, from Lat. *de*, down + *minare*, to lead, drive). The name given by English common law to every crime below the grade of felony (q.v.). By the common law, the offense of greatest enormity is treason, and the least is misdemeanor. The original distinction between felony and misdemeanor consisted in the consequences of a conviction. A party convicted of felony, if capital, forfeited both his real and personal estate; if not capital, his personal estate only. A party convicted of misdemeanor forfeited none of his property. The distinction is not kept up between the two classes of crimes by any greater severity of punishment in felony, for many misdemeanors are punished as severely as some felonies. But it has been the practice of the Legislature, when creating new offenses, to say whether they are to be classed with felony or misdemeanor; and when this is done, the above incidents attach to the conviction accordingly, in the absence of legislation to the contrary.

Misdemeanor, in the United States, does not include, in its legal application, offenses against police regulations, city by-laws, and the like, though in common language and in some statutes it may extend to any misbehavior. It is evident that what is a statute felony in one State may be a misdemeanor in another, and it is therefore impossible to give a complete classification of such offenses. They may be crimes against public justice, peace, health, or trade; against personal or property rights of individuals; or may be mere attempts and solicitations.

In some States it is provided that upon acknowledgment of satisfaction by the injured party, in such cases as assault and battery or malicious mischief, the criminal proceeding shall, with the consent of the magistrate, be dropped—a course which, obviously, would be improper in dealing with felonies. Misdemeanors are usually punishable by fine or by imprisonment for a comparatively short term, as from a month to a year, or by both, and are not rated as in-

famous crimes. See **CRIME**; **FELONY**; **CRIMINAL LAW**.

MISENO, mĕ-zā'nō (Lat. *Misenum*), CAPE. A promontory projecting into the Bay of Naples on the northwest and connected with the mainland by a narrow strip of coast, 9 miles southwest of Naples, 3 miles from the ancient Baie (Map: Italy, F 1). On the outskirts of the promontory are the scanty ruins of the ancient city of Misenum, including the Piscina Mirabilis, a huge reservoir with a well-preserved vaulted roof, supported by pillars, the Grotto Dragonara, a subterranean vaulted structure, of uncertain use, a theatre, baths, villas, and inscriptions. Misenum was made by Augustus the naval station for a division of the Roman fleet, and for that purpose a great harbor with three basins was constructed, of which the inner is now a lagoon, the Mare Morto. The town was destroyed by the Saracens in 890 A.D. Consult J. Beloch, *Campanien* (2d ed., Breslau, 1890).

MISENUM. The ancient name of **MISENO**.

MISE OF AMIENS, mĕz ov á'mé'ān' (OF., Fr. *mise*, putting, expense, judgment, from Lat. *mittere*, to send). The name given to the decision of Louis IX of France, delivered as arbitrator between Henry III of England and his barons on Jan. 23, 1264. All points in dispute were decided in favor of Henry, and the Provisions of Oxford (q.v.) were specially annulled. See **MONTFORT**, **SIMON DE**; **HENRY III**.

MISE OF LEWES, lū'is. The name given to the capitulation of Henry III of England after the battle of Lewes, in which on May 14, 1264, the barons defeated and captured him. This treaty greatly limited the royal power, and upon it Simon de Montfort sought to establish a new constitution for England. See **MONTFORT**, **SIMON DE**; **HENRY III**.

MISÉRABLES, mĕ'zā'rā'bl', LES. A noted romance by Victor Hugo, begun in 1846, but interrupted by the author's political activity. It was completed during Hugo's stay in St. Peter's, Guernsey, and was published in 1862, the first part appearing simultaneously in Paris, Brussels, London, New York, Madrid, Berlin, St. Petersburg, and Turin. It formed 10 volumes, divided into five parts, entitled *Fantine*, *Cosette*, *Marius*, *L'Idylle rue Plumet*, and *Jean Valjean*. The interest centres throughout on Jean Valjean, a fallen man who achieves his own rehabilitation after long physical and mental suffering and degradation. The saintly Bishop Myriel or Bienvenu is modeled on De Miolles, Bishop of Digne; Marius represents the author's idea of himself in his youth, and the Baron Pontmercy is intended as a sketch of Hugo's father.

MISERERE, mĭz'ĕ-rĕ-rĕ (Lat., have mercy). The name, taken from its first word, of the Psalm which is the fiftieth in the Vulgate and the fifty-first in the Authorized Version; the principal one of the seven penitential Psalms. It is used on numerous penitential occasions in the Roman Catholic church and forms part of the service for Ash Wednesday in the Anglican Prayer Book. Some of the musical settings of it are famous, especially three which are repeated annually in the Pope's Chapel during the Tenebræ.

MISERERE. A projection on the under side of the seats of the stalls of mediæval churches, chapels, and other ecclesiastical buildings. They are usually ornamented with carved work and are so shaped that when the seats proper are raised they form a support at a higher level to

a person resting upon it. Aged and infirm ecclesiastics were allowed to use these during long services.

MISFEASANCE (OF. *mesfaisance*, wrong, from *mesfaire*, *mesferre*, Fr. *méfaire*, to do wrong, from *mes-*, from Lat. *minus*, less + *faire*, from Lat. *facere*, to do). The doing of a lawful act in an improper or negligent manner; contrasted with malfeasance, the doing of a wrongful act, and with nonfeasance, the failure to perform an act which one is under a duty to perform. When misfeasance results in legal damage to a person, it amounts to an actionable tort, although the same act may be a breach of contract also, as when a common carrier injures a passenger by the negligent use of its property or improper conduct of its servants. See TORT.

MISHAWAKA, *mish'á-wá'ká*. A city in St. Joseph Co., Ind., 4 miles east of South Bend, the county seat, beautifully situated on the St. Joseph River and on the Grand Trunk and the Lake Shore and Michigan Southern railroads (Map: Indiana, E 1). It has good water power from the river and is noted as a manufacturing centre, the products including knit boots, windmills, rubber goods, plows, veneer, ladders, beer, pipe organs, cement blocks, machine-shop products, automobiles and supplies, aluminium castings, iron beds, curtain stretchers, pearl buttons, felt shoes and slippers, cigars, and leather goods. Among the prominent features of the city are the Orphans Home, hospital, public library, high school, and three fine parks. Three concrete bridges span the river at this place. The government is administered under a charter of 1899, which provides for a mayor, chosen every four years, and a unicameral council. The city operates the water works and electric-light plant. One of the oldest cities in northern Indiana, Mishawaka was settled in 1828 and was incorporated in 1834 as "St. Joseph Iron Works," the change to its present name being authorized by a special Act of the Legislature in 1838. Pop., 1900, 5560; 1910, 11,886; 1914 (U. S. est.), 14,579; 1920, 15,195.

MISHMIS. The natives of the Mishmi Hills in the valley of the Brahmaputra in northeastern India. By language they are related to the adjacent peoples of Indo-China (Chins, Shans, Lushai, etc.). These primitive tribes are very interesting from a sociological point of view. Among them the custom that the favorite child (without respect to age) inherits prevails. They are herdsmen rather than agriculturalists. Consult: Cooper, *The Mishmee Hills* (London, 1873); Dalton, *Descriptive Ethnology of Bengal* (Calcutta, 1872); Crooke, *Natives of India* (1907).

MISHNA (Heb., teaching, from *shánah*, to repeat, to teach, to learn). A juridico-political, civil, and religious code of the Jews, embodying what is regarded as the oral Law in distinction from the written Law. As such it forms a kind of complement to the Pentateuchal codes, which it explains, amplifies, and immutably fixes in accordance with traditional usage, enforced by the application of the peculiar exegetical methods developed in the rabbinical schools. The Mishnaic laws were subsequently submitted to a process of exposition similar to that which the biblical enactments underwent, and hence there arose, as a supplement to the Mishna, the Gemara (q.v.), embodying the discussions on the Mishna by the

rabbis, first of Palestine and then of Babylonia, from the third to the sixth century, when the Mishna and the Gemara had been brought together in the final compilations known as the Palestinian and Babylonian Talmuds. The rabbis whose opinions are given in the Mishna are called Tannaim. They lived at different periods from the Hasmonæan age to the end of the second century A.D. The Mishna, to which again there are apocryphal supplements known as Tosephtas (additions) and Baraitas (extras), which often are of great value, was finally edited, after some earlier incomplete collections, by Rabbi Jehudah, called ha-Nasi (c.200 A.D.) at Tiberias. It is mostly written in late Hebrew, sometimes designated as Neo-Hebraic, and is divided into six portions, or orders (Sedarim): (1) *Zeraim* (seeds), on benedictions, agriculture, tithes, etc.; (2) *Moed* (feast), on the Sabbath, festivals, and fasts; (3) *Nashim* (women), on marriage, divorce, laws on the Nazirship, and vows; (4) *Nesikin* (damages), chiefly civil and penal laws, though containing also the ethical treatise *Pirke Aboth*; (5) *Kodashim* (sacred things), sacrifices, etc., description of the temple of Jerusalem, and various other subjects; (6) *Teharoth* (purifications), on pure and impure things and persons. (See further TALMUD.) These are subdivided into 63 tracts or treatises. The Hebrew text of the Mishna was first published in Naples in 1492 with the Hebrew commentary of Maimonides, then at Venice in 1540 with the commentary of Obadiah Bartinoro, and often since. The following editions with translation into Latin or modern languages should be mentioned: Surenhusius, *Mischna* (Amsterdam, 1698-1703), containing the Hebrew text of the Mishna, with a Latin translation, and Latin translations of the commentaries of Maimonides and Bartinoro; Jost, *Mischna* (Berlin, 1832-34), containing the text, with a German translation in Hebrew characters, and notes; Sampter, *Mischnojoth* (Berlin, 1886 et seq.), vocalized text with German translation and commentary; Hoffmann and Baneth, *Die Mischna* (Berlin, 1900 et seq.), vocalized text with German translation; Albrecht, Holtzmann, Meinhold, Fiebig, Windfuhr, *Die Mischna, Text, Uebersetzung und ausführliche Erklärung* (Giessen, 1913 et seq.); single treatises by Strack with German translation. A German translation was published by Rabe at Onolzbach (1760-63); an Italian translation by Castiglione's in course of publication (1904 et seq.); and 18 treatises of the Mishna were translated into English by De Sola and Raphall (London, 1843) and under the title "The Talmud" by Barclay (ib., 1878). The treatise *Pirke Aboth* was translated by Taylor, *Sayings of the Jewish Fathers* (Cambridge, 1877). Consult also the Introductions to the Talmud by M. Mielziner (2d ed., New York, 1903) and H. L. Strack (Leipzig, 1911); Bacher, *Die Agads der Tannaiten* (vol. i, 2d ed., Strassburg, 1903; vol. ii, 1890); *The Mishna on Idolatry*, edited with translation, vocabulary, and notes by W. A. L. Elmslie (Cambridge, 1911); Emil Schuerer, *Verzeichnis der Personennamen in der Mischna* (Leipzig, 1913).

MISILMERI, *mè'zèl-mà'rè*. A town in the Province of Palermo, Sicily, 10 miles south of Palermo. The castle, situated on a hill overlooking the town, commands a magnificent view of the surrounding country. The inhabitants are chiefly engaged in agriculture, the produc-

tion of oil and wine. Pop. (commune), 1901, 12,819; 1911, 11,876.

MISIONES, mē'sē-ō'nās. A territory of Argentina, situated at the northeast end of the Republic, between Paraguay and Brazil, and bounded on the southwest by the Department of Corrientes (Map: Argentina, H 3). Its area is estimated at 11,285 square miles. It has a subtropical climate and is watered by numerous small affluents of the Paraná and the Uruguay. The soil is very fertile and the varied flora comprises more than 1500 species. Most of the territory is very densely wooded, only a small portion of its area being under cultivation. The chief products and articles of export are cabinet woods, sugar, *yerba maté*, or Paraguay tea, tobacco, corn, rice, cotton, fruits, and hides. In the seventeenth century the Jesuits planted in and around the present territory over 30 missions. With the expulsion of the Jesuits their missions fell into decay. The population of the territory in 1900 was 32,521; in 1912 (est.), 45,174. The capital of the territory is the thriving town of Posadas on the Paraná, with a population of about 15,000.

MISKO'A. A remarkable order of the Chætopoda, discovered by Walcott in the Middle Cambrian rocks of British Columbia, where the fossils are preserved with all details of structure. They are Polychæta, having similar segments and parapodia throughout the length of the body, with a retractile proboscis and straight enteric canal. Their primitive structure is shown in that their body is not distinctly specialized into sections. Striking types of the order include *Miskoia* and *Wiwaxia* (q.v.). They are named after Misko Pass in British Columbia.

MISKOLCZ, mīsh'kólts. The capital of the County of Borsod, Hungary, situated in the valley of the Szinva, 88 miles northeast of Budapest (Map: Hungary, G 2). It has several interesting ecclesiastical buildings, among them the thirteenth-century Reformed church of St. Stephen, a Minorite convent, a merchants' hall, a Protestant Gymnasium and two lower Gymnasias, a fine hospital, and a Hungarian theatre. It is lighted by electricity and has a fine municipal bath. The trade in wine, agricultural products, and cattle is considerable. The local manufactures consist of flour, shoes, pottery, porcelain and majolica wares, and machinery. There are large wine cellars in the neighborhood. Pop., 1900, 43,096; 1910, 51,459, chiefly Protestant Magyars.

MISNOMER (OF. *mesnomer*, *mesnommer*, dialectic Fr. *ménomer*, misname, from *mes-*, from Lat. *minus*, less + *nomer*, name, from Lat. *nominare*, to name, from *nomen*, name). An error in naming a person in a pleading, deed, or other written instrument. Under the common-law rules of pleading a party intended as the defendant in an action can take advantage of a mistake in designating him by an incorrect name by a plea in abatement which simply alleges the error and states his true name. However, in England and the common-law jurisdictions in the United States this defect may now be cured by amendment if the person so served appears in the action, even though he pleads the misnomer. Where a person is served with a process intended for him but not designating him by his correct name, he may disregard it, and a valid judgment cannot be entered against him. Under modern codes of procedure the same rules

apply, except that if a person is served with a summons incorrectly naming him, and he desires to appear and object, he must make a motion to set aside the service on the ground of mistake. In such a case the plaintiff will be allowed to amend his summons and complaint, usually upon terms, such as the payment of costs. The term "misnomer" is less frequently but correctly applied to a mistake in a name in written instruments other than pleadings. See INTERPRETATION; EQUITY; MISTAKE; NAME; PLEADING; WILL; ETC.

MISPICK'EL (Ger.). See ARSENOPYRITE.

MISPRISION, mīs-prīzh'ūn (OF. *mesprision*, *misprison*, mistake, from *mesprendre*, to mistake, from *mes-*, from Lat. *minus*, less + *prendre*, from Lat. *prendere*, *prehendere*, to take). In its general sense, a crime under the degree of a capital offense but graver than an ordinary misdemeanor (q.v.). In the early English law it was more frequently employed in a negative or passive sense, to describe the omission to perform some important legal duty, as concealment of the felonious acts of another. It is also applied to certain positive acts in the nature of contempts against the dignity and peace of the King and his officers. Misprision of treason was the most serious offense to which the term applied, and consisted in the concealment of any knowledge which a person might have of treasonable acts or utterances against the King, and did not necessarily imply that the person was himself otherwise implicated or involved in the crime. It was formerly punishable with forfeiture of goods and imprisonment for life, but by statute forfeiture of goods has been abolished, and penal servitude for life remains the maximum statutory penalty. Misprision of felony is concealment of a felony by one who did not participate in its commission by act or encouragement, but who has learned of it in some way. It is still an offense in the English law, but is rarely prosecuted. The various acts and omissions, other than the above, which were formerly included in the rather vague term "misprision," have been mostly classified with the crimes with which they were associated, under the name of accessory acts.

The term "misprision" is seldom employed in the United States except in regard to treason, and by an act of Congress misprision of treason is punishable by a fine not exceeding \$1000 and imprisonment not exceeding seven years. See ACCESSORY; CRIME.

MISREPRESENTATION. An untrue representation, by words or by conduct, which induces another to act to his injury. When deliberately or recklessly made by one party to a business transaction concerning a matter of fact and relied on by the other party to his damage, it amounts to fraud (q.v.), or deceit (q.v.). A false representation, if made by an honest mistake, never subjects the maker to an action in tort. Whether it will afford the party to whom it is made a ground for relief of any kind depends upon the circumstances of the case. As a rule, an innocent misrepresentation will not affect the validity of a contract in connection with which it is made, unless it was the very basis of the contract or one of its material terms.

In certain classes of contracts, notably those of marine and fire insurance (q.v.), any misrepresentation or concealment of a material fact, however innocent, renders them void. This is

due largely to the fact that such contracts have come into English law from the law merchant, and that early mercantile usage put an absolute legal duty on the insurer to state correctly all facts relating to the thing insured, which would ordinarily affect the insurer's decision in taking the risk. Courts of equity deal somewhat differently with innocent misrepresentation from courts of common law. They will generally refuse a decree for specific performance in favor of one whose claim rests upon a misrepresentation, although it is an honest one; and in some cases they grant a rescission of a contract induced by such statements when in a court of law the contract would be enforceable. Consult: Anson, *Principles of the Law of Contract* (Oxford, 1900); Burdick, *The Essentials of Business Law* (New York, 1902); Kerr, *A Treatise on the Law of Fraud and Mistake* (London, 1902).

MISRULE, LORD OF. A mock dignitary who presided over the Christmas revels of the Middle Ages. He was assisted by a staff of from 20 to 60 officials, and furnished with musicians, dragons, hobbyhorses, and other paraphernalia of fun. In Scotland the Lord of Misrule was sometimes known as the Abbot of Unreason, and in France as l'Abbé de Liesse. See **ABBOT OF JOY**.

MIS'SAL (ML. *missale*, from *missalis*, relating to the mass, from *missa*, mass). The book which contains the prayers, lessons, and rubrics of the mass in the Roman Catholic church. Until the Middle Ages the various parts of the service were distributed in separate books, according to the part taken by the assistants; the parts which the celebrant alone recited in the mass and other sacraments were contained in the *Liber Sacramentorum*, or sacramentary. But when low masses became more frequent, and the celebrant had to say practically the whole service, the parts were collected into one book called *Missale Plenarium*. These complete missals have been in use since the sixth century. By the twelfth the Roman liturgy was in use generally throughout western Europe, but a number of provinces and dioceses had their own missals. The disadvantages of this diversity in liturgical use caused numerous requests to be made to the Council of Trent for a reform in the matter. The Council appointed a commission on the subject in 1562, and as they had not concluded their labors by the last session, left the decision in the hands of the Pope. The commissioners, among whom was Thomas Goldwell, Bishop of St. Asaph in Wales, were not instructed to compile a new missal, but by examination of ancient manuscripts to reconstruct the Roman missal according to the rites and customs of the fathers. Pius V authorized the missal which was the result of their work by the bull *Quo Primum* of 1570, commanding its universal use in places which could not show a prescription of 200 years for their local uses. Thus the older orders, such as the Carthusians and Dominicans, preserved their traditional rites; and the Ambrosian missal held its ground in the diocese of Milan. Further revisions took place under Clement VIII in 1604 and Urban VIII in 1634; later revisions, as by Leo XIII in 1884 and 1898, have touched merely matters of detail, principally in the rubrics. Besides these and the tables which are in the beginning of the book, it includes the proper of the seasons, i.e., the service for the Sundays and greater festivals; the proper of saints, arranged in the

order of the civil calendar from St. Andrew's Day, which regulates the beginning of Advent and thus of the ecclesiastical year; and the common of saints, the services for those days which have no special mass. The central and invariable parts, known as the *Ordo* and *Canon Missæ*, come before the service for Easter Day. The older local missals, especially the French and English, are of great interest to liturgical students. No new attempts have been made to construct such books in the Catholic church except by some French bishops under Jansenist influence about the end of the seventeenth century; these held their own in certain places even as late as the middle of the nineteenth century, when they were all laid aside, largely through the influence of the celebrated scholar Dom Guéranger. Consult William Maskell, *The Ancient Liturgy of the Church of England, according to the Use of Sarum, York, Hereford, and Bangor* (3d ed., Oxford, 1882). See also **LITURGY**, and references given there; **MASS**.

MISSEL THRESH. See **MISTLE THRESH**.

MIS'SI (Lat., those sent). Officials sent out by the Frankish kings for special purposes. Under Charles the Great the *missi dominici* were the Emperor's special representatives. The Empire was divided into a number of districts; into each district each year two *missi*, one a lay noble, the other an officer of the Church, were sent to hold court, hear complaints, redress grievances, and make a special report to the Emperor. By this means Charles sought to control the courts and to centralize the government. The *enquêteurs*, employed by St. Louis, had similar functions. Consult Dobbert, *Ueber das Wesen und den Geschäftskreis der Missi Dominici* (Heidelberg, 1861), and J. W. Thompson, *Decline of the Missi Dominici in Frankish Gaul* (Chicago, 1903).

MISSING LINK. A term used to designate the stage assumed to intervene in evolution between the ape and man, and in a more general sense any hypothetical form intermediate between two actual forms of life.

MISSION (Lat. *missio*, a sending, from *mittere*, to send). In the singular, a term used by Roman Catholics and Anglicans to designate a series of special services lasting usually for at least a week, intended to call sinners to repentance and to deepen the spiritual life of the faithful; somewhat analogous to the revival services in some other churches. In the Roman Catholic church such work was constantly carried on by some of the most famous saints, such as Francis of Assisi, Dominic, Carlo Borromeo, Francis de Sales, Vincent de Paul, and Alfonso Liguori. The last two especially founded their congregations (see **LAZARISTS**; **REDEMPТОRISTS**) for such a purpose. In modern times the means employed and the order of exercises have become more systematic. Fervent preaching by the missionaries, who are usually members of some religious order, is the salient feature; it deals largely with sin, repentance, death, judgment, heaven and hell, and its purpose is to bring the hearers to a devout reception of the sacraments and an earnest Christian life. It usually closes with a solemn service of renewal of baptismal vows, thanksgiving, and consecration, and with the proclamation of a special indulgence. In the last third of the nineteenth century similar missions were held with increasing frequency in the Anglican communion, especially in High Church parishes.

MISSION, CONGREGATION OF THE. See LAZARISTS.

MISSIONARY RIDGE, BATTLE OF. See CHATTANOOGA, BATTLE OF.

MISSION INDIANS. A collective term for the surviving remnants of the tribes civilized and Christianized by the efforts of the Spanish Franciscan missionaries in southern California in the latter part of the eighteenth century. They were originally of many various dialects and stocks, chiefly Shoshonean and Yuman, roving over the desert and mountain region stretching from the lower Colorado River to the Pacific, and in almost the lowest stage of culture. By the heroic and persistent labor of Father Junipero Serra and his successors, beginning in 1776, they were gathered into civilized communities, where they supported themselves by farming and simple mechanical arts and, under the kindly supervision of the fathers, reared those magnificent mission structures which are the glory of old California. For half a century the missions grew and flourished, until in 1831 they contained 19,000 civilized Indians, but with the overthrow of the Spanish power by the Mexican revolutionary government came oppression, spoliation, and finally confiscation and destruction in the period from 1835 to 1840. The missionaries were banished, the missions plundered and left to fall into ruin, and the Indians driven into the desert and the mountains. Under the later American rule the remnants of the mission Indians continued to be regarded and treated as outcasts until, chiefly by the endeavor of Helen Hunt Jackson (q.v.), public attention was so forcibly directed to their neglected and unfortunate condition that the government took steps for their relief by setting aside some small reservations for their occupancy and appointing an agent to look after their affairs, together with a good school equipment. Since then some progress has been made towards bringing them up to the standard to which they had attained under the mission system more than a century ago. The two great barriers in the way are the uncertain tenure of their lands and the monopoly of the water supply by white claimants. At present they occupy a number of small reservations in southern California. The total population is about 2000. They are best known as the makers of fine baskets. Consult: Jackson and Kinney, *Report on the Condition and Needs of the Mission Indians of California* (Washington, 1883); C. A. Wetmore, *Report on Mission Indians of Southern California* (ib., 1895); Zephyrin Engelhardt, *Missions and Missionaries of California*, vol. i (San Francisco, 1908); "A Mission Record of California Indians," in *University of California, Publications: American Archaeology and Ethnology*, vol. viii (Berkeley, 1908).

MISSIONS, CHRISTIAN. The term "missions" as used in this article signifies Christian missions among the peoples of non-Christian countries. The history of missions may be divided into three periods: 1. The early period, embracing the first seven centuries of our era, until the rise of Islam. In this period missionary activity was generally unorganized and individual. 2. The middle period, including nine centuries, from the beginning of the eighth to the end of the sixteenth century. Here the Church as an organization originated and directed foreign-missionary activity. 3. The modern period, from the beginning of the seventeenth

century until the present time. In this period occurred the rise of Protestant foreign missions, chiefly conducted by voluntary societies.

I. THE EARLY PERIOD

The energy of the Apostles in winning men to believe in Jesus Christ is a characteristic feature of the New Testament narrative of the beginnings of Christian history. Early traditions give ground for belief that their missionary operations were extended. Yet excepting in the case of Paul and his companions details are meagre. The explanation of the rapid spread of Christianity seems to be that individual believers taught it wherever they went, whether for business, for safety from enemies, or as slaves to heathen masters. Great importance was attached also to translating the Bible into the language of every people at this period. Examples of this automatic spread of Christianity may be seen in its appearance in Antioch before any Apostle went there, its entrance into Italy before Paul's visits, into Britain by way of Gaul from Smyrna during the second century, along the ordinary routes of trade, and into the bivouacs of the Goths in the third century through captives taken in war. By the time of Constantine the Great, early in the fourth century, groups of Christians were found in all parts of the Roman Empire, from Britain to Persia. Christians formed but a small percentage of the population. But they had a high ideal and the energy of aspiration. This produced unflagging activity in missions in the West and in the East. The monasteries now performed great services for religious culture in out-of-the-way places. In the fifth century the centre of missionary initiative for the West seems to have been in central Gaul. Thence bishops went over into Britain to help the Christians settle doctrinal difficulties, and thence Patrick took his new-found knowledge into Ireland. For the East at the same time the centre of missions seems to have been in Mesopotamia, at places like Edessa and Nisibis, with a long chain of advance posts reaching into central Asia and India, and with a training school at Samarkand. Towards the north at the same period Ulfilas (q.v.) went on a mission to his heathen kin in the region of the Danube, giving them an alphabet and a Bible in their own tongue. In the sixth century the initiative in the West was from the British Islands eastward and from France northward. Desire to teach Christ brought Columba from Ireland to Iona, which became a wonderful centre of Christian culture and of missionary zeal in behalf of Scotland, North Britain, and central Europe. As to the East, the line of foreign missionary advance was among the Tatars and in China, and was carried on by Nestorians in relations with the Church in Mesopotamia. At the very end of the sixth century the beginning of a missionary policy in the Church as an organization appeared in the dispatch of Augustine (q.v.) and his helpers from Rome to England, where the Saxon invasion had nearly crushed out Christianity. Augustine's mission from the Pope was to evangelize the pagans and to win the assent of the English Christians to Roman ecclesiastical control. The method of operation of these independent missions was an adaptation of the monastic system. A band of Christians under a leader would form a settlement in a wild and savage

region, where they labored for their own support. By kindness some of the barbarians would be drawn to settle near the monastery. After the favor of emperors began to give the Church numerical preponderance, power, and wealth, these gains led to spiritual loss, and missions were left to the chance ability of simple-minded believers in remote regions. At the beginning of the seventh century Christianity was still an Oriental religion. In Europe its northern bounds were, in general, marked by the Danube and the Alps, although during the century missionaries made ineffectual attempts at a lodgment in Denmark, and Columban, going forth from Iona with his associates, began a fiery and successful propaganda among the barbarians of central Europe. The narrow limits of European Christendom at this time should be borne in mind if we would realize the full meaning to the Christian Church of the Mohammedan irruption. The Eastern church had one momentous mission to its credit in the ninth century in its dispatch of Cyril and Methodius to work among the Slav races. In the Far East the Nestorians also continued their operations until the Tatars finally cast in their lot with Islam, and Tamerlane in the fourteenth century destroyed the last vestiges of the Central Asian church. But with regard to the Church in general, from the end of the seventh century onward for 900 years the only Christian foreign missions were remote from the touch of the Mohammedan power and belonged to the Western or Latin section of the church.

II. THE MIDDLE PERIOD

1. **In Germany.** The wanderings of the Germanic nations and the inroads of the Huns had destroyed along the Rhine and the Danube the flourishing Christian communities of the fifth century. It was only after the rise of the Frankish state that efforts were made to restore the former condition of Christianity and to spread its influence over all central and northern Europe. From the conversion of the Bavarians to that of the Saxons (500-800) stretches a period filled with spiritual heroism on the one side and with tenacious resistance on the other. The missionaries are mostly Irishmen in the first half of the period, Anglo-Saxons in the other. The memory of the famous St. Severin (died 482) worked favorably in Bavaria; early in the sixth century the royal family of the Agilulfings was Catholic. Irish missionaries worked in the land throughout the seventh and eighth centuries. The Frankfort saints Ruppert, Emmeran, and Corbinian continued and perfected their labors. The Irishman St. Gall (Callech) was the apostle of Swabia and Helvetia; from his monastery by Lake Constance went out the missionaries of these lands. At the same time his superior and long-time companion, Columban (died 615), converted the German Lombards of Italy to the Catholic faith. Southern Germany owes the knowledge of the Christian faith to other Irish missionaries—St. Fridolin, once abbot at Poitiers and then founder of the island abbey of Säkingen; St. Trudpert, founder of the abbey of that name in the Breisgau; St. Pirmin (died 753), founder of Reichenau, Murbach, and Hornbach. The Irishman St. Kilian (died 689), with his companions Coloman and Totnan, evangelized Thuringia, and founded the see of Würzburg. Contemporaneously St. Willibrord came from the

monastic schools of Ireland to preach the faith to the fierce Frisians and to found the archbishopric of Utrecht, with the authorization of Pope Sergius I (695). Before Willibrord there had worked along the Rhine and the Moselle the holy man Goar in the sixth century, and among the Frisians St. Amand of Maastricht (660) and the goldsmith St. Eloi (Eligius) of Noyon (659). All of these men came under the influence of the Columban monastery of Luxeuil and were filled with missionary zeal.

The real apostle and founder of German Christendom is the Anglo-Saxon Wynfrith, or Boniface (q.v.). In 716 he attempted to evangelize the Frisians. In 719 he received at Rome from Gregory II (715-731) the authority to preach among the degenerate Christians and the pagan inhabitants of Germany. In turn he labored throughout Bavaria, Hesse, and Thuringia, and along the Rhine, founded the oldest and principal sees of those regions, established monasteries like Fulda, and gathered about himself some of the noblest spirits of the age. The Carolingians were always friendly and helpful. In union with them he held, between 740 and 750, four national synods that laid the basis of German mediæval Christian life. He suffered martyrdom June 5, 755 (1754), at the hands of heathen Germans, near Dokum in West Friesland, whither he had gone with 52 companions to confirm some newly baptized converts. The solid mass of Saxon paganism had been attacked by the two Ewalds, surnamed the Black and the White, like Willibrord, disciples of the Irish monastic schools. They sealed their hopes with their blood in 695. The long wars of the Carolingians with the Saxons soon took on a religious character. Compulsory baptism and swift apostasy were the rule throughout the eighth century. A cruel slaughter of 4500 Saxons at Verden in 782 stains the fair fame of Charlemagne. The conquered Saxons were exiled, transplanted, oppressed by laws of Draconian severity; in 785 the dauntless chiefs, Witikind and Alboin, finally yielded, and by 804 the land was entirely Christianized. Missionaries soon overran Saxony, and by their virtue, beneficence, organizing skill, and their monasteries, soon established the Christian faith on a firm basis. The abbey of Corvei (822) was soon the centre of their activity.

2. **Among the Northern Nations.** Another period of 300 years (800-1100) was necessary for the winning of the northernmost Germanic tribes. In 826 political necessity made Harald, King of Denmark, a suitor at the court of the Carolingians. On his return he took with him Ansgar, a monk of Corvei, eventually the apostle of the North. His chief deeds were the establishment of the see of Hamburg-Bremen (832), the partial evangelization of Sweden (850), the building of churches, schools, monasteries, and hospitals throughout his own vast diocese. He died in 865 and is buried at Bremen. The devastations of the pagan Northmen and the onslaught of the Hungarians withheld from the northern missions the political influence of Christian Germany; after the battle of Merseburg (933) the conversion of Denmark went on, not without interruption, from the see of St. Ansgar. The Danish conquests in England helped this process; in 1017 both kingdoms were ruled by Canute the Great; in 1026 he was a pilgrim to Rome, whence he wrote to his people a noble Christian letter. In 1066

another Canute was enrolled among the Christian saints. In 1104 Lund was made a metropolitan see. Sweden was slowly won over to the faith of Jesus Christ, chiefly in the course of the eleventh century, and with many a reaction to pagan life and belief. In 1162 Upsala became the Christian metropolis of Sweden. Long ere this Norway possessed a metropolitan see at Trondhjem (1035). The land was thoroughly Christian before Denmark and Sweden, although it received the visits of missionaries after both of these kingdoms. Haakon the Good (c.934-960) was an earnest Christian King, but another did not arise until Olaf Tryggvason (995-1000). Olaf Haraldson (1016-28) sent German and English priests through the Kingdom; his over stern and cruel policy created a reaction, but the still harder yoke of Denmark favored the cause of Christianity. From 1035 Norway may be styled a Christian kingdom. Iceland was temporarily inhabited by Irish monks before the year 800; their books, altar plates, and staves were found by the first Norwegian settlers. After 981 Christianity penetrated the masses of the colonists and by 1016 they had accepted the Gospel. Under its impulse this gifted little people became a living source of learning and piety. The scattered islands of the northern seas were held during the ninth century in the grip of the pagan vikings, but in the course of the tenth century were made Christian. Before the epoch of the Danish invasions of Ireland monks of the Irish nation had visited these islands, chiefly out of ascetic fervor and the desire to lead hermit lives. They were the first to bring Christianity to the dwellers of the Orkneys, the Hebrides, and the Shetland and Faroe islands. In the twelfth century Greenland was evangelized and the see of Gardor established on the coast; the land was inhabited by Christians until the fifteenth century.

3. Conversion of Eastern Europe. Slavs and Magyars. As the Slavs had been, since the sixth century, a serious menace to both the East and the West, so the efforts to Christianize them went out from East and West. The Irishman St. Columban, of Luxeuil and Bobbio, had once hoped to begin the work; it was certainly set on foot from the German see of Salzburg in Bavaria, and a beginning made (797) with the Avars, who at this time disappear from history. In the course of the ninth century the principal Slavic principality was that centred along the river Morava, hence called Moravia. Both Germans and Byzantines sought to reserve this sphere of influence and action for themselves. In 862 the Byzantine Emperor, Michael III, was able to send two missionaries to the Moravians. They were brothers, known to history as St. Cyril (originally Constantine) and St. Methodius. They introduced among the Slavs an alphabet, translated the Scriptures, and wrote for them a Slavic liturgy. To these two men the Slavic world owes its first permanent elevation from idolatry, ignorance, and serious moral corruption. Moravia's chief see, Olmütz, dates from 1063.

Bohemia was fully opened to Christian influences only about 871, when its King, Borzivoi, gave his daughter in marriage to Svatopluk of Moravia and, together with his Queen, Ludmilla, was baptized. Of his grandsons, Boleslas cruelly persecuted the Christian faith, while Wenceslas remained faithful; the latter fell by

the hand of his brother (938), and is honored as a martyr. In the long reign of the second Boleslas (967-990) Christianity triumphed. The see of Prague was created in 973. The second Bishop, St. Adalbert, went to preach the gospel among the heathen Prussians, and was put to death by them.

Poland received the missionaries of Christianity through the marriage (965) of its Duke Miecislav with the Christian daughter of Boleslas II of Bohemia, who soon won over her husband to the faith. The see of Posen was established in 968. From 992 to 1025 Boleslas Chrobry, son of Miecislav, completed the conversion of his country by the founding of the archiepiscopal see of Gnesen (1000), to which were made subject Posen, Kolberg, Breslau, and Cracow.

The Wends were a Slavic race, established in Holstein, Mecklenburg, between the Elbe and the Oder, the Oder and the Vistula, and elsewhere in Saxony and Lusatia. They were made Christians by the creation of the border marches in the time of Henry I and Otho I (919-973) and the foundation of the sees of Havelberg, Oldenburg, Brandenburg, Magdeburg, and others (946-968). The Wend Prince, Gottschalk, was after 1045 a zealous protector of Christianity, but was treacherously slain in 1066 by a heathen Wend. In the twelfth century the Wends fell under German sway and many German Christian colonists took their lands and houses. The Wends of Pomerania owe their conversion to the Polish Duke Boleslas III (1122) and to his agent, Bishop Otho of Bamberg (1124-28). Kamin, Stettin, Julin, were made Christian cities and Saxon colonists entered the territory; but only in 1168 were the last remnants of heathenism abolished on the island of Rügen.

The Scandinavian Rurik founded the Russian state in 862; soon Christian missionaries from Constantinople found their way thither. The widowed Princess Olga was baptized at Constantinople in 955 and thenceforward labored zealously for the conversion of her people. Her grandson, Vladimir the Apostolic (died 1015), completed the work. The metropolitan see of Kiev was established by him and made the centre of the religious and educational life of Russia. The primacy was transferred to Moscow in 1328, which in turn was subject to the jurisdiction of Constantinople until 1589, when Jeremias II, the patriarch of the latter see, was induced to install the patriarchate of Moscow.

Bulgaria became Christian, 864-866. The Khan, Bogoris, first introduced Greek missionaries and then appealed to Pope Nicholas I. The latter sent him the famous "Replies to the Consultations of the Bulgarians." Nevertheless, Bulgaria soon came under the sole jurisdiction of Constantinople; the land was subjected by the Byzantine emperors, and in 1388-93 the new Bulgarian realm was conquered by the Turks.

The heathen Magyars had taken possession after the end of the ninth century of what is now Hungary. All attempts at their conversion were fruitless until the victory of Otho the Great of Germany on the Lech in 955. Duke Gejza (972-997), married to a Christian Princess of his own race, asked Otho II for missionaries; the bishops Pilgrim of Passau and Wolfgang of Regensburg were sent to him. Gejza's

son, St. Stephen of Hungary (997-1038), was married to Gisela, the daughter of Henry II. He created the hierarchical system of Hungary by founding (1000) the archiepiscopal see of Gran with 10 suffragan sees, as well as many Benedictine monasteries. Pope Sylvester II (Gerbert) gave him the title of "Apostolic" King, and is said to have sent him a golden cross and crown (crown of St. Stephen).

4. **Missions in Northeastern Europe. Political Conversions.** The power of Christendom was now too great to be longer resisted by the outlying heathen peoples. From Sweden went out at the same time the political subjection of Finland and its conversion to Christianity. It was only in 1293 that the work could be looked on as accomplished. Eathonia, Livonia, and Courland saw Christian missionaries during the twelfth and thirteenth centuries follow in the tracks of the German merchants of Bremen and Lübeck. Here the heathen were fierce and reluctant; fortified monasteries protected the German Christians and the newly converted, until, in 1202, was founded the military order of the Brothers of the Sword (*Schwertbrüder*) or Knights Sword Bearers. Its founder, Bishop Albert of Buxhöwden, built the city of Riga and set up therein his see. In 1237 the Brothers of the Sword were united with the Teutonic Knights of Jerusalem, and for 60 years both orders carried on an unceasing warfare against the pagan inhabitants of the Baltic shore. Their most difficult conquest was that of the Prussians. This most stubborn of the northern heathen folk gave way only before the organized and experienced knights of German Christendom and the moral and financial support of the Empire. In 1243 the Prussian territory was divided into four sees—Kulm, Pomerania, Ermland, Samland; in 1255 they were placed under the jurisdiction of the archiepiscopal see of Riga. The Lithuanians, temporarily converted in 1252, relapsed into heathenism. Their Grand Prince, Jagello, married in 1386 the Polish Queen Hedwig, by which act Poland and Lithuania were shortly made one politically. Jagello was baptized, assuming the title of Ladislas II. Vilna was made an episcopal see, and at a diet held there Christianity was declared the state religion.

5. **Missions in the Sixteenth Century.** (a) *In the Orient.*—The Portuguese sailors and the merchants were always accompanied by missionaries. As early as 1533 Goa was made an episcopal see. The unworthy conduct of the Europeans was no small obstacle for the missionaries when confronted with such religious systems as those of the Brahmans, Buddhists, and Mohammedans. At the request of the King of Portugal St. Ignatius of Loyola destined for the East Indies in 1540 Rodriguez and St. Francis Xavier. The latter actually sailed in 1541 from Lisbon, and after some time spent in evangelizing the Europeans of Goa, turned his attention to the people of southern India. He preached in the Kingdom of Travancore, and went thence to Malacca and the Moluccas, meeting everywhere with great success. Soon his zeal urged him to undertake the conversion of Japan, where he spent two years (1549-51). In the hope of hastening the conversion of Japan, he turned his attention next to China, but died on the way on the island of Sancian, in November or December, 1552. His labors in the East Indies were continued by his Jesuit brethren,

especially by Robert Nobili, after 1606. The latter made himself one with the Indian aristocracy, accepted its prejudices, habits, and customs, so far as seemed consistent with Christianity, and enjoyed a large measure of success.

The Nestorian missions in China during the seventh and eighth centuries and the Franciscan missions of the thirteenth and fourteenth had no lasting results. In 1583 the Jesuits obtained entrance, and for over a century exercised a moral supremacy in the Flowery Kingdom. Matteo Ricci (1552-1610) rose to the highest official position. His teaching, surveys, and maps were the admiration of all China.

Adam Schall of Cologne (1622) and Ferdinand Verbiest of the Low Countries (1659) won great fame for their order as successors of Ricci. Under cover of their reputation for scholarship they labored zealously for the spread of Christianity, quite in the spirit and manner of Robert Nobili. The opposition to this system of "accommodation" grew so strong that it was condemned in 1704, and the condemnation was confirmed 40 years later (1744) by the holy see. The Christian communities of Japan were grievously persecuted in 1587 and again from 1596 to 1637, when the Empire was strictly closed against all foreigners, with the exception of Dutch traders.

(b) *In America.*—The original Spanish conquistadores were very inhuman towards all nations with whom they came in contact. The first Catholic priest ordained in the New World was a young Spanish lawyer, Bartolomeo de las Casas. He soon gave himself entirely to the work of saving the Indians from their barbarous oppressors; and before his death, in 1566, he had compelled the legislation which saved the remnants of the aboriginal tribes, at least on the mainland. Similarly, St. Peter Claver (died 1654) was tireless in the service of the unfortunate negro slaves of South America. Throughout the sixteenth century Dominicans, Franciscans, Capuchins, and Augustinians labored with boundless zeal in all the Spanish colonies. The Jesuits were already in Brazil (1549), and soon had their missionaries in all parts of South America. The famous "Reductions of Paraguay" are perhaps their greatest triumph. One of the most picturesque figures of that period is the Limerick Irishman, Thomas Filde, a Jesuit, who died at Asunción in 1626, after spending 40 years among the savages of Paraguay. In North America the French missionaries followed the flag of France and worked unremittingly after 1611 throughout all the dominions over which it floated. In 1634 Jesuit missionaries accompanied the first colonists of Maryland.

III. THE MODERN PERIOD

A. **Protestant Foreign Missions.** 1. *State Missionary Enterprises.*—At the time of the Reformation Christendom was still beleaguered by armed Islam. Up to the very end of the seventeenth century a great part of Hungary was in the possession of Turkey, and in 1683 Vienna barely escaped falling into the hands of the Mussulmans. Missionary access to eastern north Africa and western Asia was barred by the sword of Islam. At the same time transmarine heathen lands were so distant that imperial resources alone could reach them. Such resources were all in the hands of the great Roman Catholic powers. The conditions under

which the Reformation developed left to the reformers no place for planning foreign-missionary enterprise. Luther and his associates appreciated the essentially missionary quality of the Church of Christ, but limited its sphere of action to their own surroundings. They deemed that in any case the Church was helpless regarding foreign missions, since such vast undertakings could be dealt with by governments alone.

The first Protestant foreign missions, then, were state enterprises. In 1555 Admiral Coligny induced the Council of Geneva to send missionaries to Brazil in connection with a Huguenot colony, but both mission and colony soon ended in bloody disaster. In 1559 Gustavus Vasa of Sweden sent missionaries to labor for the pagan Lapps of his own dominions, but this mission came to naught. After the conquest by Holland of several Portuguese colonies in the East Indies the Dutch East India Company was formed in 1602, and the governors of the various islands were ordered to do all in their power to Christianize the natives. Clergymen were sent out to Ceylon, Formosa, and the Malay Archipelago as missionary chaplains, whose duty included the Christian instruction of natives. But the governors of the colonies obeyed their orders literally and "Christianized" the natives without waiting for the missionaries to instruct them. Consequently, when Dutch government came to an end in Ceylon, some 300,000 officially converted natives returned to their former faith. In Formosa Christianity was extinguished by the Chinese when they drove the Dutch from the island in 1661. In Java, however, the missionary chaplains slowly translated the Scriptures into Malayan. The second of modern Bible translations into pagan languages (John Eliot's Indian Bible, printed in 1683, being the first) was thus produced by the initiative and published (in 1701) at the expense of the Dutch government. With all its defects this state mission enterprise had permanent results. In Java, the Moluccas, and Celebes has grown up a native Christian church, numbering nearly 250,000 adherents, with over 350 pastors and preachers, supported by the Dutch government. Of these probably not more than half are the fruit of later missionary efforts. A similar mission undertaken by Holland in Brazil, through the West India Company, about the year 1621, came to an end with the expulsion of the Dutch about the middle of the century. Such missionary enterprises undertaken for reasons of state, manned by official appointment, and supervised by colonial bureaus and chambers of commerce, were foredoomed to failure. The next of the state missionary enterprises originating on the continent of Europe illustrates this fact. In 1705 a woman whose husband had been killed by natives in the Danish colony of Tranquebar, in South India, petitioned King Frederick IV of Denmark to send missionaries to teach the people there. The petition was effective. The King endowed the mission, and, no fit men being found in Denmark, two Germans were appointed to go to India. They were of the disciples of Francke, the German pietist, who saw that the highest form of Christian fruitfulness includes foreign as well as home missions, and whose energy formed schools at Halle to prepare men to serve Christ in the ends of the earth. The two young men, Ziegenbalg and Plutschau, taught singleness of purpose at Halle, and sent

out by King Frederick IV in 1706, began the first serious Protestant mission enterprise in India. Before his death, in 1719, Ziegenbalg had made a translation of the New Testament into the Tamil language, which became the basis of the existing Tamil Bible, and the third modern translation of the Scriptures into heathen languages. Other missionaries from the same home surroundings followed the two pioneers of this Danish mission, notably Schultze and his later associate, Schwartz. Each of these men made a permanent impression upon the people of the country. Fifty thousand Tamils became Christians before the end of the century. After the death of King Frederick IV the English Society for the Promotion of Christian Knowledge assumed the whole support of the Danish mission in India until 1824, when the enterprise was passed over to the Society for the Propagation of the Gospel. Another mission maintained by King Frederick IV was that commenced by Hans Egede in Greenland in 1721. It was later transferred to the Danish Missionary Society, and the whole Eskimo population in the neighborhood of the numerous Danish trading stations was long ago Christianized.

The British government took steps early in the seventeenth century for the Christianizing of its colonies. The Virginia Company, whose enterprise began in 1584, was directed by its charter to teach Christianity to the Indians, and Sir Walter Raleigh subscribed £100 to that object. The same duty was laid upon the Massachusetts Colony by charter in 1628. In 1646 the Legislature of Massachusetts passed a law for missionary work among the Indians. This gave State support to the efforts of John Eliot of Roxbury, Thomas Mayhew of Marthas Vineyard, and others. In 1648 Cromwell induced the English Parliament to consider the organization of a government foreign-missionary enterprise. The renewal of civil war, however, put an end to the scheme. But the Corporation for the Propagation of the Gospel in New England, formed in England in 1649, received a grant from Parliament and aided Eliot's mission. It still exists under the name of the New England Company, and expends the revenue from its endowment funds for the education of Indians in the Dominion of Canada. All these efforts resulted in the formation of several villages of converted Indians in New England before progress was arrested by war. In the East Indies, on the renewal of the charter of the British East India Company in 1698, the duty was imposed upon the company of maintaining chaplains at its stations, and later the obligation to see that its native servants were instructed in Christian doctrine. Discussions regarding religious conditions in the company's stations led to the organization in 1698 of the Society for the Promotion of Christian Knowledge (S. P. C. K.), designed to provide Christian schools and books for neglected English communities. This was followed three years later by the organization of the Society for the Propagation of the Gospel in Foreign Parts (S. P. G.), designed to provide chaplains for the religious culture of Englishmen in foreign lands. Neither of these societies aimed at Christianizing the heathen. But the S. P. C. K. saved the Danish mission in South India from dying with its founder, and supported it for 100 years. It has also issued

Christian literature in the languages of various non-Christian peoples. As to the S. P. G., it gradually took up work among the pagans, and in 1913 it had 1291 missionaries and 3000 native workers in India, China, Japan, Malaysia, Africa, and the West Indies. In view of their later history, these two societies may be regarded as the earliest of the voluntary foreign-missionary societies of Great Britain.

2. *Protestant Voluntary Missionary Societies.*—In 1709 the state of the North American Indians led to the formation, in Scotland, of a Society for the Promotion of Christian Knowledge. The chief present importance of this society was its employment as a missionary (in 1744) of David Brainerd of Connecticut. The story of his brief life had persuasive influence on both sides of the Atlantic in stimulating similar devotion. A more powerful influence of the same nature was exercised by the writings and the example of the Moravian Brethren, who called themselves the Unity of Brethren. A remnant from persecution, this little people migrated from Bohemia and in 1772 found asylum in Germany. They were allowed to settle on the estates of Count Zinzendorf, who was himself a pupil of Francke of Halle and who became their leader. The Brethren established missions among the slaves of the West Indies, in Greenland, among the Indians of the North American Colonies, in South Africa, in South America, and in Labrador before the end of the eighteenth century. More recently they have opened missions in Australia, Alaska, and on the borders of Tibet. In 1900, all the Eskimos at their four stations in Greenland having become Christians, they transferred their Greenland mission to the Danish church. In their other fields they had in June, 1914, 367 European and American missionaries, 111 native missionaries, and 2059 native workers.

Through such influences and through the writings of Spenser and Francke in Germany and the earnest exhortations of Whitefield and Wesley in England (who had themselves been deeply affected by the writings of Francke and Zinzendorf), and of Jonathan Edwards in America, a resuscitation of personal religion was brought about. At about the same time the travels of Captain Cook revealed the immense extent of the heathen world, while occurrences like the trial of Warren Hastings and the antislavery agitation of Wilberforce brought home to the minds of the English people their responsibility for outrages perpetrated by purely selfish men professing the name of Christians. The time was ripe for action to benefit the sufferers from such outrages. As early as 1779 the English Wesleyans sent a number of missionaries among the North American Indians, and in 1786 they began a mission in the West Indies. In 1814 these beginnings were followed by the organization of a society which has supervised the mission work of that church up to the present time. Its missions lie in Ceylon, India, South Africa, Oceanica, and China. In 1913 this society had in the field 695 missionaries of both sexes, aided by 4826 native workers. In addition there is the Wesleyan Methodist Women's Association, with 108 women missionaries aided by 320 native workers. In general, however, the sudden development of foreign-mission enterprises about the beginning of the nineteenth century did not come from any Church organization. It sprang from the awakening of isolated

individuals whom the Church opposed as unsteady enthusiasts. In 1786 William Carey, a cobbler and a Baptist minister in England, surprised a ministers' meeting by proposing discussion of the duty of foreign missions. He was frowned down by his elders. In 1792, however, he commanded attention and won support. The duty had become plain. In that same year 12 men united to form the Baptist Missionary Society, sending Carey and Thomas as their first missionaries to India. The East India Company would not tolerate missionaries, but they found a safe residence in the Danish colony of Serampore, near Calcutta. The influence of the mission was immediate. Carey's greatest work was that of Bible translation; and the Serampore press, under his direction, added to the slender list then existing translations of Scripture in 34 languages. The Baptist society extended its work in India and added to its field Ceylon, the West Indies, West Africa, and China. In 1913 it had in the field 363 missionaries, men and women, with 905 native workers. The Baptist Women's Missionary Association had (1913) 90 women missionaries and 450 native workers. The example of the English Baptists had effect in all Protestant countries. The reading of Carey's first letters from India led in 1795 to the formation of the London Missionary Society (L. M. S.), in which Independents, Presbyterians, Methodists, and Episcopalians united. Since the other denominations have undertaken missions of their own, this society is now composed substantially of Independents alone. Its present fields are Oceanica, South and Central Africa, Madagascar, India, and China. In 1914 it had in the field 294 missionaries, men and women, and 7480 native workers. Nott, John Williams, Morrison, Medhurst, Rice, Moffat, and Livingstone are names which give special lustre to its roll. In 1796 two similar societies were formed in Scotland, which served at first as auxiliaries to the London society. Later they did good work by themselves in South Africa and the West Indies, and afterward became merged in the missionary societies of the Established church and the United Presbyterian church of Scotland. The formation of a society in Holland in 1797 (called the Netherlands Missionary Society), to aid in the work of the London society, illustrates the solidarity of Christian feeling which underlies the modern missionary movement, and also the failure at first to appreciate the extent of the work committed to a single board of directors by Christians of different denominations and nationalities. The Netherlands Missionary Society furnished several missionaries to the L. M. S., and afterward chose its special field in the Dutch East Indies, where in 1913 it had 65 missionaries and 135 native workers. From this beginning a score of other societies in Holland have sprung for direct and indirect foreign-missionary work. Meanwhile the claims of freed slaves at the Sierra Leone colony were pressed upon the Church of England. Pious men in the employ of the East India Company, like Brown and Grant, urged that church to labor among the people of India. Nothing being done by the church in 1799, 26 of its spiritually minded members, among whom were William Wilberforce, John Venn, and Charles Simeon, organized the Church Missionary Society (C. M. S.), at first known as the Society for Missions to

Africa and the East. They at once encountered opposition on the ground that such enterprises should be directed by the bishops, which made it difficult for them to find fit ministers to go out. Hence the society drew its early missionaries from Germany. Altogether more than a hundred of its missionaries have been Germans, many of them of the highest ability, like Krapf, Rebmann, Rhenius, and Pfander. Nearly half a century passed before the C. M. S. won recognition from the episcopate. The fields of the C. M. S. are in India, Ceylon, China, Japan, West Africa, East Africa and Uganda, Mauritius, Arabia, Persia, Palestine, Egypt, Sudan, and the northern and western parts of British North America. In 1914 it had in the field 1340 missionaries, men and women, and 10,325 native workers, of whom 454 are ordained clergymen. The growth of English interest in missions, combined with the successes of the Halle missionaries of India, led in 1800 to the establishment at Berlin of Jannicke's Missionary School. This school during the next quarter of a century furnished some 80 missionaries to the English and Dutch societies, and served to arouse further interest in missions in Germany. Meanwhile the same ideas were working in America. They found expression in foreign missions through the devotion of Samuel J. Mills and other students at Williams College, who agreed together to give their lives to preaching to the heathen. The earnestness of these young men led to the formation, in 1811, of the American Board of Commissioners for Foreign Missions (A. B. C. F. M.), an interdenominational society. The first missionaries of this society, Newell, Judson, Hall, Rice, and Nott, were sent to India, and were instantly ordered out of the country by the East India Company. Judson and Rice joined the Baptists at Serampore, and the others after some trouble succeeded in getting a footing in Ceylon and at Bombay. Within 10 years the society had occupied other fields in India, in Hawaii, and in Turkey. After some 40 years of existence as an interdenominational society it relinquished some of its fields in India, Persia, Syria, and West Africa to the American Dutch Reformed and Presbyterian churches, who wished to conduct separate missions of their own. It is now supported chiefly by Congregationalists. The A. B. C. F. M. has missions in China, India, Ceylon, South Africa, West Africa, Japan, Turkey, and Oceanica. In 1912 the number of its missionaries, men and women, was 615, with 4999 native workers. Judson and Rice, of the first group of missionaries sent to India by the A. B. C. F. M., changed their views on baptism before entering upon their work, and chose Burma for their field of labor. This occurrence led in 1814 to the formation of the American Baptist Missionary Union (A. B. M. U.) to assume the support of the two pioneers in Burma. Its present fields are in Burma, Siam, Assam, India, China, Japan, the Philippines, and the Congo Free State. In 1913 it had in the field 701 missionaries of both sexes, with 8589 native workers.

The success of the early missionaries of these English and American societies aroused an interest which extended to the Protestants of the continent of Europe and led in 1815 to the establishment of a missionary institute at Basel in Switzerland. The training school for missionaries with which this institute began its

operations provided valuable men for the English societies. A magazine for missionary intelligence, published by the institute, deepened missionary interest in Germany and other Protestant countries. In 1822 the Basel institute began to send out missionaries, one of the earliest of whom, Zaremba, labored effectively in Russian Armenia until expelled by the Russian government in 1835. Its present fields are in West Africa, India, and China, and graduates of its school are pastors of evangelical churches in Turkey. In 1913 it had in the field 442 missionaries, men and women, with 1911 native workers. The land of Luther had already contributed men and means for foreign missions during many years before its first foreign-missionary society was formed at Berlin in 1824 by 10 men of mark, among whom were Neander and Tholuck. Following the conservative usage of the continental Protestants, the first work of the Berlin Missionary Society was to establish a training school for missionaries. It began to send men abroad in 1834. Its present fields are in South Africa, German East Africa, and China. It has also done much to draw Christian colonists to the German colonies. In 1912 it maintained 181 men as missionaries in its various fields, with 1339 native workers. During the first part of the nineteenth century a considerable number of little missionary associations had been formed in different parts of Germany to aid existing societies at Basel and elsewhere. Later these developed into the Rhenish, the North German, the Leipzig, the Gossner, and the Hermannsburg Missionary Societies, and have finally won the support of the official representatives of the Church to what is now a large and important missionary enterprise in Africa, India, China, Malaysia, and Australasia. The foreign missions of the Protestants of France began in 1818 with a missionary magazine intended to give information of the work of missionaries of other nations. This was followed in 1824 by the organization of the Evangelical Missions Society of Paris, designed at first to aid existing missions. Since 1825 it has sent missionaries of its own to Central Africa and Senegambia, besides replacing, in consequence of French national prejudices, missionaries of the L. M. S. in Tahiti and Madagascar and American missionaries in the French Congo region. It had, in 1914, 119 European missionaries in its service. The roots of the existing missionary societies in Denmark, Norway, and Sweden also lie in the first quarter of the nineteenth century. These Scandinavian societies expanded during the last quarter of the century, and in 1913 they had 287 men and 395 women missionaries, assisted by 2858 native workers, in Africa, Madagascar, India, China, and Chinese Turkestan. The intimate relations of some of the Scandinavian societies with German, English, and American enterprises, however, make it certain that some of these missionaries are also reported by societies in other countries. In 1824 the Established church of Scotland undertook missionary work in India and among the Kaffirs in Africa, one of its early missionaries being Alexander Duff, the father of educational missions. The disruption in 1843 caused the resignation of all the Scotch church missionaries in India and Kaffraria, they preferring to join the Free church, which has since carried on extended missionary operations. In

1900 the Free church joined with the United Presbyterian church in forming the United Free church of Scotland. This body has missions in India, Africa, Arabia, Syria, Turkey, China, West India, and the New Hebrides. It had, in 1913, 545 missionaries, men and women, and its force of native workers is 2842. As to the Established church of Scotland, after recovering from the effects of the disruption, it pressed its missionary enterprises, and in 1913 it had in India, Central Africa, China, and Turkey 116 missionaries of both sexes, with 244 native workers. These Scottish mission enterprises are carried on by the Church organizations, and not by independent missionary societies.

The Bible societies grew out of the same religious quickening which gave rise to the voluntary missionary societies (the British and Foreign Bible Society, 1804, the American Bible Society, 1816, the Netherlands Bible Society, the Scottish National Bible Society, and others). So far as concerns their publications in the languages of non-Christian peoples these societies do foreign-missionary work in the very highest sense, since no Protestant foreign mission can exist without the Bible in the language of the people among whom it is working. The Bible societies work in harmony with each other and with the missions. Indeed, missionaries have made the greater part of the translations of the Bible now in circulation. The Bible or parts of it existed in 1914 in almost 600 different forms of speech. The British and Foreign Bible Society has a list of 474 different languages. The Religious Tract Society of London (1799) and the American Tract Society of New York (1820) have done a similar work for foreign missions in adding to provide general Christian literature in the languages of non-Christian lands.

While our survey indicates the origin of the Protestant missionary movement in the spiritual enlightenment of the Christian Church, it cannot detail its expansion since the first quarter of the nineteenth century. In the second quarter of the century the Methodist church and the Presbyterian church in the United States, previously occupied with missions among the American Indians, began their great missionary enterprises abroad. In many other denominations in the United States, Great Britain, and Europe, foreign-missionary undertakings have been organized. Since the middle of the century foreign-missionary societies have been formed in the colonial churches in Canada, the West Indies, India, Australia, New Zealand, South Africa, and other Protestant colonies. Since 1861, when the first Woman's Foreign Missionary Union was formed in New York, Christian women in all lands have entered upon the work, organizing women's missionary societies, commonly more than mere auxiliaries to the older enterprises. Educational and medical missionary enterprises have been established in considerable number. Interdenominational missionary societies, like the Christian and Missionary Alliance of America and the China Inland Mission and the North Africa Mission of England, have undertaken extensive enterprises in non-Christian countries. To some extent Christian communities which are themselves the fruit of missions have undertaken foreign missions: as in India, Africa, the Fiji Islands, the Hervey Islands, and Hawaii. In India, Ceylon, and South Africa the Salvation

Army has established itself, seeking to forward the evangelization of the heathen by methods peculiar to itself. The Student Volunteer Movement, organized in 1886 in America, but now found in many other lands has done much for the increase of mission interest among students. In 1914 the various missionary societies united in the formation of a Board of Missionary Preparation. Missions have fostered a sense of Christian unity. In India, China, and Japan, and in some other countries, interdenominational conferences of missionaries are regularly held. In south India and Japan union churches have been formed. In the Netherlands, in Germany, in the United States, and to some extent in Great Britain, conferences between the various Protestant missionary societies are held at regular intervals. General and international missionary conferences have been held, of which the last and most important was held at Edinburgh in 1910.

3. *Methods and Problems of Foreign-Mission Work.*—As to the methods used in the presentation of the gospel experience has developed certain principles, almost attaining to the quality of a science of missions. Preaching in the language of the people is the first and most important method of evangelization; and the establishment of a permanent preaching place, to which all may come if they choose, is a first concern in every missionary station. Need at once appears to place the Bible in the hands of the people. This fixes literary work as another method of evangelization. Qualified missionaries translate the Bible, set up presses and print it, prepare helps to its study, tracts, and general Christian literature, and in short apply the enormous influence of the printing press to the enterprise of making Christ known. In 1913 the British and Foreign Bible Society published 1,170,000 Bibles and portions in India and Ceylon, 2,183,000 in China, 300,000 in Africa, and 633,000 in the Japanese Empire. The American Bible Society in the same year printed 29,579 Bibles, 134,689 Testaments, and 2,573,120 portions abroad. Desire that the people shall read requires not only the printing of primers, but the establishment of schools. But every school gives unsurpassed facilities for moral and spiritual culture, and this in proportion to the importance of its general training. Hence educational work has an importance as a method of evangelization which is immeasurable where the quality of instruction is of the best and the spiritual power of the teachers is of the highest. In 1910 there were, under the direction of Protestant missionaries, 30,300 primary schools and kindergartens, with 1,295,954 pupils of both sexes, and 2624 higher educational institutions, with 204,128 students; 86 of the last-named institutions are universities and colleges attended by 8628 students of both sexes. Theological and normal schools and training classes had 12,761 enrolled in 1910; boarding and high schools, 166,447; industrial training institutions and classes, 16,292. Medical work is another powerful method of evangelization. Protestant foreign missions in 1910 possessed 576 hospitals and 1077 dispensaries, in which 4,235,375 individuals received treatment during the year. A most pervasive method of evangelization is consistent Christian living. This includes not only Christian family life, which in itself is an object lesson for non-Christians, but also social intercourse with the people and a

wide variety of works of philanthropy, both in times of famine and pestilence and in the daily contact of ordinary life.

As soon as converts have been won, there arises the problem of their organization and culture as a body having self-control, initiative, and the power of expansion. The results of missionary work cannot be permanent unless the Christian Church becomes indigenous on the foreign field. Hence the members of native churches must early be accustomed to manage their own affairs and to support their own church institutions and their schools. Missionaries rarely become pastors of the local churches, and in general avoid settling local ecclesiastical questions except in conjunction with the local ministers.

Whatever the ability and common sense of the missionary, attack is probable upon him by vested interests represented in the religion of the country where he would preach. The murder, during 1900, of 135 British, Swedish, and American missionaries in China was a tragedy of missions more than once paralleled in quality, though not recently in degree. In this connection a problem arises as to the right of missionaries to ask government protection. It is generally held that missionaries should not depend upon such protection; that they go among savage tribes at their own peril, and that in lands where laws and treaties exist they must obey the laws. On the other hand, a government jeopardizes the right of all its people residing in any foreign country when it neglects to defend such of them as are maltreated while engaged in lawful occupations.

4. *Results of Missions.*—General statistical tables of Protestant foreign missions are seldom perfect. Nevertheless, the following figures may be taken as a fairly accurate statement of the activities of the various missionary societies operating from the countries named for the year 1914.

COUNTRIES	Stations and outstations	Men and women missionaries	Native laborers	Communi-cants	Added last year	Under instruction	Income
United States.....	14,802	6,282	39,825	972,655	110,194	†450,158	\$11,549,390
Canada *.....	461	509	796	15,582	1,061	6,969	563,998

* For 1910.

† Including teachers.

Again, foreign missions have not merely planted Christianity in all the principal non-Christian lands of the world; they have added the Bible to the literature of all the great languages of the earth, placing before the eyes of the people the principles of true manhood and its model in the peerless figure of Jesus Christ. The British and Foreign Bible Society in 1913 issued a total of 8,958,233, the American Bible Society 5,251,176, and the National Bible Society of Scotland a total of 2,697,886 Bibles, Testaments, and other parts of Scripture. Results of missions visible to the eye in non-Christian lands, but not capable of record in statistics, are the overthrow of degrading superstitions, the limitation or extinction of immoral and cruel customs, the modification of non-Christian religious teaching, the gradual elevation of the standing of woman, the quickening of general intelligence, and the wide introduction

of education among illiterate and degraded races, together with the addition of great territories to the area of the world's commerce. To this must be added the work done by missions in charitable care for the sick, the blind, the lepers, and outcasts of every class.

Bibliography. For early missions: J. Wyse, *A Thousand Years; or, The Missionary Centres of the Middle Ages* (London, 1872); Charles Merivale (ed.), *Conversion of the West* (5 vols., New York, 1879); L. C. Barnes, *Two Thousand Years of Missions before Carey* (Chicago, 1901); George Smith, *Short History of Christian Missions* (Edinburgh, 1904). For modern missions, the reports of the societies, annals of particular missions, and lives of individual missionaries, constitute a great mass of material. A bibliography of this literature to the end of 1890 by S. M. Jackson may be found in E. M. Bliss, *Encyclopædia of Missions* (New York, 1891, 2d ed., ib., 1904), continued by J. S. Dennis in his *Foreign Missions after a Century* (New York, 1893). For a general view of the missionary operations of various societies and discussions of the theory of missions, consult the *Reports of the World Missionary Conference in Edinburgh in 1910* (New York, 1910). For the history of Protestant missions: G. A. Warneck, *Abriss einer Geschichte der protestantischen Missionen von der Reformation bis auf die Gegenwart* (8th ed., Leipzig, 1904; Eng. trans. by John Robson, *Outline of the History of Protestant Missions*, 8th ed., Edinburgh, 1906). For the study of the mission fields and the results of missions: J. S. Dennis, *Christian Missions and Social Progress* (3 vols., New York, 1897-1906); the appendix to this work, *Centennial Survey of Foreign Missions* (ib., 1901), has a very complete collection of statistics; also Dwight, Tupper, and Bliss, *Encyclopædia of Missions* (ib., 1904). For more general discussion: W. N. Clarke, *A Study of Christian Missions* (New York, 1900); E. T. Churton, *Foreign*

Missions (London, 1901); A. T. Pierson, *The Modern Missions Century* (ib., 1901); E. A. Lawrence, *Modern Missions in the East* (Chicago, 1901); Andrew Murray, *The Key to the Missionary Problem* (New York, 1902); R. E. Speer, *Missionary Principles and Practice* (ib., 1902); H. H. Montgomery, *Foreign Missions* (ib., 1902); H. P. Beach, *Geography and Atlas of Protestant Missions* (ib., 1902-03); R. A. Hume, *Missions from the Modern View* (ib., 1905); L. M. Hodgkins, *Via Christi: An Introduction to the Study of Missions* (ib., 1910); J. S. For the spread of the Church during the first three centuries, the authoritative history is G. A. Warneck, *Die Mission und Ausbreitung des Christenthums in den ersten drei Jahrhun-*

derten (Leipzig, 1902). For medical missions: John Lowe, *Medical Missions* (New York, 1891); V. F. Penrose, *Opportunities in the Path of the Great Physician* (Philadelphia, 1902); H. O. Dwight, *Blue Book of Missions* (New York, 1905-07), is a pocket compendium of statistics and other missionary information. See also the various publications of the Student Volunteer Movement.

B. Roman Catholic Foreign Missions. 1. Central Administration. *The Congregation of the Propaganda.*—In a general way the direction of all Roman Catholic missions is vested by the holy see in the Roman congregation *De Propaganda Fide*, established in 1622 for Roman Catholic missions by Gregory XV. It consists to-day of 25 cardinals, with a cardinal prefect as their head, and a number of prelates and consultors in charge of the various details of administration. The congregation has at Rome its own palace or bureau, a college, a library and museum, a polyglot printing press, and certain fixed revenues, chiefly from domestic or Italian sources. The various missions are distributed by it according to the character of its subjects and the nature of the religious orders to which they belong. It settles finally all disputes between missionaries, whether they regard territorial jurisdiction or the conduct of the missionary work. The regular reports made by missionary bishops or superiors to the holy see pass through the congregation, and in general it acts as agent for missionaries in all matters that regularly pertain to other Roman congregations; e.g., questions of Tridentine law, marriage and divorce, criminal questions, and the like. Its principal meeting is on the first Monday of every month. A weekly meeting is regularly held for minor matters. Among the most important attributes of this congregation is the selection of bishops. Where there is a regularly established hierarchy, a list of three names is submitted to the Propaganda with all the documents pertaining thereto. These candidates are discussed in the regular monthly assembly of all the resident cardinals, and he who seems the most worthy is proposed to the Pope. This privilege of recommendation, in whatever way it be exercised, differs entirely from the election of a bishop, which belongs to cathedral churches by virtue of the regular canon law. In some countries, as in Canada, and formerly in the United States, the provincial bishops alone recommend the three candidates. In other countries, as in England, Scotland, and Ireland, the clergy or the chapter (i.e., the canons of the cathedral), as the superior part of the clergy, draw up a list which the bishops of the province confirm with their approbation or reject with animadversion on one or the other or all of the candidates. Elsewhere, as in the United States since 1884, and in Australia, the clergy or representative part of the clergy recommend three names to the bishops of the province, who in turn recommend these or others to the holy see. When there is no regular hierarchy vicars apostolic are appointed, with episcopal character, from a list of three names drawn up by the superiors of the religious institute or order to which the care of the faithful has been already committed. In the absence of such action the Pope appoints a vicar apostolic on recommendation of the Propaganda. On account of the rapid growth of Catholicism, chiefly in English-speaking countries, the office of Cardinal Prefect of the Propaganda has become one

of the most important and responsible of the great curial offices; he is often called the Red Pope.

The College of the Propaganda is an institution attached to the congregation for the purpose of training its missionaries from their very youth. It owes its first beginnings to the Spaniard John Baptist Vivés, who bequeathed to it his palace at Rome and made it his heir. Since 1622 the original foundation has been greatly enlarged. Urban VIII was a notable benefactor of the work (1641); hence it bears the name of Collegium Urbanum. Some canons of the Lateran Church were the first teachers of the young missionaries, but the college soon passed into the complete control of the new congregation. It was endowed with many privileges by the popes. They exempted it from all ordinary ecclesiastical and civil jurisdiction, and several special distinctions were granted it, among others the right of giving degrees in theology and philosophy. Its present quarters were designed by Bernini, and the chapel is the work of Borromini. Seven months after their entrance the candidates for the missions are required to take an oath of obedience to the congregation; among other things they promise to go directly to their respective missions after ordination. Those who remain as missionaries in Europe (e.g., in the British Isles, the northern kingdoms, Switzerland) are required to report annually to the prefect of the congregation; those whose missions are elsewhere must write to him biennially. Not a few candidates, especially from the Orient, come at an early age. Such youths do not take the missionary oath until after they have reached their fourteenth year. In this college the training is the usual seminary training. Only, for the beginners, Greek and Latin, and especially the suitable Oriental languages, make up the curriculum. The college owns near Rome its own country seat or villegiature, whither the students go during the heated season. On Pentecost one of the students of the college preaches before the Pope and the cardinals. Its students at the end of the eighteenth century were about 140; at present they do not exceed 120. The French Revolution caused it to close its doors; but since 1809-17 it has been opened for its former work, and many distinguished men have graduated from its classes. From 1836 to 1848 the teaching and discipline were under the control of the Jesuits. Since then they are provided for directly by the congregation itself, which names a rector and vice rector with other officials, and provides for the programme of studies. Several national colleges attend the lectures of its professors—thus, the North American, Canadian, Irish, Greek, Ruthenian, and other national ecclesiastical schools frequent its classrooms. Yearly an *Accademia Polyglotta* is held on the first Sunday after Pentecost. Discourses, poems, and addresses are then read in a great variety of languages, chiefly Oriental, and the ceremony is graced by the presence of many dignitaries of the Roman court. Lately new and commodious quarters have been secured for the academic needs of the college.

The congregation has long owned and managed a printing press that is unique on account of the many kinds of type it possesses for the Oriental languages. In the last two centuries a multitude of Oriental texts have come from its offices—liturgical, ascetic, literary, theological, patristic, historico-religious. There is perhaps no

where else in the world an Oriental printing press so well equipped and so scientifically conducted. It issues regularly a catalogue of its publications, and is officially known as the *Stamperia de Propaganda Fide*.

The Congregation of the Propaganda governs all Catholic missions according to the general law of the church, the decrees of the Council of Trent, the decisions of other Roman congregations, the papal rescripts, and the conciliar legislation. But over and above the ordinary law there is a certain amount of special legislation for the missions and missionaries. As early as 1669 the Propaganda issued its *Advice to Missionaries*, that has been lately reprinted (*Monita ad Missionarios*, Rome, 1874). The details of its extensive legislation are to be found in the collection of its document known as the *Bullarium* of the congregation (Rome, since 1839, 5 vols., folio; with an index, 1858). Another collection is that of Raphael de Martinis (7 vols., folio, Rome, 1889-1900). The particular legislation of the Propaganda affecting the Oriental missions is found in the work entitled *Collectanea Constitutionum, etc.* (Paris, 1880) and in the *Apparatus Juris Ecclesiastici* of Zephyrin Zitelli (Rome, 1886). Occasionally the congregation issues a legislation that modifies the regular canonical procedure in justice, e.g., in the trial of matrimonial cases, clerical delicts, and other judicial processes. Such documents then become norms of ecclesiastical government in the land for which they are issued. The current public documents of the congregation may be easily found in the Roman canon law periodical entitled *Acta Sanctæ Sedis*, and those of the Pope in the annual series of pontifical documents respectively known as *Acta Pii IX*, *Acta Leonis XIII*, etc.

Usually the establishment of a remote and difficult mission begins with the sending of a prefect apostolic by the Pope, at the suggestion of the Congregation of the Propaganda. As a rule this missionary is only a priest, but he receives certain special authorizations from the holy see, e.g., the right to administer confirmation. As soon as the conditions of the mission warrant, a vicar apostolic is appointed to take charge of its interests. Such a missionary is made a titular bishop, i.e., he is given the "title" of some see extinct or suppressed. No specific seat of residence is fixed for him; he organizes the mission as best he can. In time sees are established with territorial limits, and canonical obligation of residence for the bishop; thus a quasi-normal condition arises in which the administration of spiritual affairs gradually grows quite like that of the older Catholic states of Europe, and the regular ecclesiastical law tends to obtain as against the temporary and opportunist administration of an earlier date. Nevertheless, for various reasons, the holy see often continues to govern such well-developed churches through the Congregation of the Propaganda, instead of incorporating them in the ordinary system of its administration. The Propaganda is thus one of the busiest of the Roman congregations. There come before it all questions that arise in missionary lands concerning the creation of dioceses, their dismemberment, division, union, and transformation; the nominations to episcopal office; the relations, in last resort, of bishop and clergy; all questions between bishops and religious orders, and between orders themselves in matters of their mission work; the

discipline and supervision of national missionary colleges, theological seminaries in missionary lands; the regular reports of its bishops, their special needs or plans, and similar things. It is in close contact with all other Roman congregations, to which it acts as a kind of clearing house for the missions and missionaries. Its juridical decisions are final, authoritative, and reversible only by the Pope, to whom they are always submitted beforehand when the gravity of the occasion or the nature of the problem in question warrants. The congregation has a permanent secretary, generally an archbishop, who goes weekly to the Vatican with the proceedings of the congregation, to submit them to the approval of the Pope and give such explanations as are needed. This office is looked on as "cardinalitial," i.e., as leading directly to the dignity of cardinal—hence it is always filled by an ecclesiastic of learning and experience.

A large and valuable library is connected with the congregation, for its own use and for the needs of the college and the printing press. It is especially rich in ancient theology and philosophy, and in all kinds of Orientalia, both printed and manuscript. It is accessible to students and writers. The archives of the congregation are kept with care, and are of great value for the ecclesiastical and civil history of the missionary lands. They are partially accessible under certain conditions, and are now being used by historians of the sixteenth, seventeenth, and eighteenth centuries, especially for the period of the Counter Reformation in Germany, Switzerland, and the Netherlands.

Until 1862 the affairs of all the missionary churches, East and West, were treated in one and the same Congregation of the Propaganda. In that year Pius IX established a special section of the congregation for the administration of the Oriental churches (*Sacra Congregatio pro Negotiis Ritus Orientalis*). It has its own chief, a *Cardinalis Ponens*, and its own officials and counselors. To each curial (resident) cardinal of this section is allotted the conduct of the religious affairs of some one of the Oriental rites united with the holy see; he is called the *Cardinalis Relator*.

2. *National and Particular Direction*.—The principal national missionary enterprises of Roman Catholics are carried on from Paris and Lyons in France. The most venerable of them is the Seminary for Foreign Missions (*Missions Etrangères*), founded at Paris, 1658-63, and located in the Rue du Bac. Its missionaries are under the guidance of local superiors (bishops) throughout China, Chosen (Korea), Tibet, Turkey, Siam, Burma, and Hindustan. In the seminary is a curious and touching *Musée des Martyrs*. The annual departure of its missionaries from Paris gives occasion for a remarkable popular ceremony and demonstration. The Society for the Propagation of the Faith (*Œuvre de la Propagation de la Foi*) was founded in Lyons in 1822 by a few pious lay persons. Its object is not to train or send out missionaries, but to collect and distribute for missionary purposes funds received from private generosity. This distribution is carried out without distinction of location or nationality, a principle which from the beginning differentiated this organization from previous enterprises of a similar nature. The receipts for the year 1822 were scarcely \$4000. In 1898 the association collected nearly seven millions of francs and the total

amount raised by the society in the various countries (France being always far in advance of the others) from the beginning down to 1912 was \$80,349,653. By 1915 it had amounted to \$83,634,380. The society was established in the United States in 1840, and down to 1912 had collected \$3,031,129. Up to 1915 the society had spent \$6,478,714 in the United States. The means adopted for the raising of funds is the payment of five cents per month by the members enrolled in the association. The Work of the Holy Childhood (*Euvre de la Sainte Enfance*), a related enterprise, has collected and spent about \$10,000,000. Other French associations for missionary help are the Work of the Oriental Schools, the annual collection on Good Friday for the Holy Land, the Work of the African Missions, the Anti-Slavery Association, the White Fathers, the Fathers of the Holy Ghost—all works established originally in France and extended to different parts of the world.

There are many religious orders and institutes in France which send numerous members to the mission fields; thus, there are some 800 French Jesuits in the Orient, and they carry on excellent colleges at Beirut, Cairo, and Alexandria. Similarly Lazarists, Dominicans, Assumptionists, and others have numerous missionaries scattered through the Orient. The Christian Brothers have many well-attended schools in Egypt, Syria, Asia Minor, at Constantinople, and in the Levant. Owing to colonial expansion, Catholic Germany has shown more interest in missions during the last three decades, though the earlier French "Works" always found sympathy in Germany. The Bonifacius-Verein (1849) for home missions has spent in the 65 years of its existence over \$7,000,000. The Ludwigs-Verein (1839), the Leopolda-Verein (1839), the Afrika-Verein (1894), the Association for the Holy Land (1893), and other enterprises have kept alive the zeal of German Catholics for the conversion of the heathen. A large number of the German Catholic missionaries are Jesuits. Within the last decade an increasing German missionary activity is manifest, especially in China and Brazil, in which latter country the German colonists increase at a rapid rate.

The French "sisterhoods" give generously of their members to the Oriental missions. Most of the missionaries to the credit of Catholicism are Frenchmen; a still larger proportion of the Catholic "sisters" on these missions is made up of Frenchwomen. Perhaps 10,000 is not too high a number. Of the entire number of congregations of men and women that labor in Catholic missionary fields, over 80 are of French tongue or have their home in France.

While the Spanish missionaries have nearly all taken their way to the Philippines, the Italian missionaries carry on, in an hereditary way, certain lines of work in the Orient, notably in the Levant. Statistics of their number and work are not easily reached. The Salesian Fathers (Turin) of Don Bosco turn their energy towards South America, and the society founded by Bishop Scalabrini, of Piacenza, is especially interested in the Italian population of South America and the North American cities. Holland has had a house for foreign missions at Steyl since 1875, with about 120 missionaries. At Mill Hill, in England, the English Catholics support a seminary for missions among the blacks. The College of All Hallows at Dublin draws its missionaries from Ireland; many of

them come to the United States and merge into the American clergy; Ireland makes provision also for a few missions in Africa and India.

As to the civil relations of the Catholic missions in the Orient, France was their official intermediary with the local governments until the separation of church and state in France, Dec. 9, 1905. This ancient privilege was recognized by late acts of the Prefect of the Propaganda and the Holy Father. It was also recognized anew by the Chinese Emperor in March, 1899. Among the notable acts in the history of Oriental Catholic missions was the establishment by Leo XIII of a regular hierarchy in India (1886) and in Japan (1891).

The support of Catholic missions comes almost entirely from private sources. The money salary of each missionary is a very modest one. The Work of the Propagation of the Faith at Lyons allots annually from \$100 to \$120 to each missionary that it supports. Nearly all the money comes from small contributions, but through a well-organized system of collection.

There are in all some 55 Catholic orders and societies engaged in missionary work, ranging in date of foundation from the Benedictines in 529 to the Foreign Missionary Society of Turin in 1900. Among those most prominently engaged in missionary activities are the Benedictines, Cistercians (Trappists), Dominicans, French Foreign Missions, Minor Franciscans, Capuchin Franciscans, Jesuits, Lazarists, Mazarists, and Oblates of Mary Immaculate. In addition there are over 30 orders of brothers and 175 orders of sisters engaged in mission work as auxiliaries to the missionary priests. There are some 12,000 priests, 4000 teaching brothers, and 40,000 sisters. The entire force of workers in the Catholic missions field now numbers over 60,000.

3. *Some Important Events and Facts in the History of Modern Roman Catholic Missions.*—As a result of the loss of its East Indian possessions the crown of Portugal became involved, during the last century, in long and serious conflict with the holy see. From 1834 to 1838 the latter cut off from the original Portuguese archdiocese of Goa four vicariates apostolic, that coincided with English territory. Though absolutely just and necessary, this act of Gregory XV was resented by Portugal. A schism followed which lasted more or less acutely and continuously until 1886, when peace was brought about by Leo XIII. Goa was made a titular patriarchate with four suffragans, Damão, Archbishop also *ad honorem* of Cranganor, Cochim, St. Thomas of Meliapur, and Macao. Elsewhere in India the former vicariates apostolic of Agra, Bombay, Varapoli, Calcutta, Madras, Pondicherry, and Colombo (Ceylon) were raised to the archiepiscopal rank and freed from all subjection to the archbishopric of Goa.

During the whole nineteenth century the Catholic missions in Tongking and Annam suffered very frequently from popular uprisings and government persecution, until the establishment of the French civil protectorate in 1885-86.

Until 1880 the Catholic missions in Korea were almost continuously the object of similar maltreatment; nevertheless, there was in 1912 a total of 52,109 native Catholics, with 129 chapels and churches, 35 foreign and 10 native priests, and 7 foreign lay brothers. There were also 10 foreign and 57 native sisters. The present religious toleration in Korea under Japanese rule

was unknown in early days. In 1839 three French bishops were put to death as martyrs, and in 1860 nine bishops suffered the same fate.

The modern Catholic missions in Japan began tentatively in 1832-58. An impetus was given by the discovery of a number of crypto-Catholics (1858-72), who had retained some souvenirs of the faith as preached to their ancestors in the sixteenth and seventeenth centuries. With the gradual enlargement of religious liberty since 1872, the disestablishment (1886) of Shintoism and Buddhism, and the proclamation of a constitutional monarchy (1889), the conditions have been more favorable for the Catholic missions. In 1891 Leo XIII established a regular hierarchy in Japan, with one archbishop at Tokio. The three suffragans are at Nagasaki, Osaka, and Hakodate. In Japan (including Korea) in 1912 there were 202 foreign and 48 native priests, 140 lay brothers, 303 sisters, 400 churches and chapels, and 144,984 Catholics.

The labors of the Catholic missionaries in China during the last century were largely directed to gathering back into the Christian fold the families scattered by the former persecutions. The opium war, the Taiping Rebellion, political manoeuvres, the weakness of the central authority, and the native hatred of the Chinese for "foreign devils" caused the destruction of many promising Christian communities in spite of the treaties of 1844 and 1850. One cause of the Boxer Rebellion of 1900 was fear of the political activities of the Catholics, especially the French orders, who were more or less supported by the French government. The present constitution of the Chinese Republic grants absolute freedom to all religions. In 1912 there were in China (including Manchuria, Mongolia, and Tibet) 1365 foreign and 721 native priests, 247 foreign and 86 native lay brothers, 743 foreign and 1429 native sisters, 9214 churches and chapels, 7131 schools, 134,057 scholars, and a native Catholic population of 1,406,659.

In Central Africa the most important events have been the labors of Father Libermann and his society (Fathers of the Holy Ghost) since 1840 and the foundation of the Pères Blancs of Cardinal Lavigier. The African missions have been helped lately by the formation of anti-slavery societies. Among the most remarkable of Catholic missionaries in Africa was Father Daniel Comboni. In Ethiopia the central figure has been the late Cardinal Massaia, a venerable Capuchin, who devoted 30 years of his life to the work. In French Africa the see of Algiers was founded in 1838, and in 1867 became an archbishopric, with Constantine and Oran for suffragans. The French protectorate over Tunis (1881) brought with it, in 1884, the restoration of the famous ancient see of Carthage. Since 1885 the French protectorate over Madagascar has affected somewhat favorably the Catholic missions among the Malagasies.

According to Streit, *Atlas Hierarchicus*, the statistics of Africa for 1912 are as follows: for northeast Africa, 266 foreign and 80 native priests, 400 brothers, 1067 sisters, 190 churches and chapels, 180 schools, 20,557 scholars, and 138,018 Catholics. For northwest Africa, 427 foreign and 5 native priests, 141 brothers, 339 foreign and 27 native sisters, 334 churches and chapels, 564 schools, 40,992 scholars, and 125,300 Catholics. For Central Africa, 810 foreign and 3 native priests, 361 foreign and 14 native brothers, 446 foreign and 31 native sisters, 2426

churches and chapels, 3306 schools, 125,449 scholars, 6410 European and 332,696 native Catholics. For South Africa, 387 foreign and 4 native priests, 360 brothers, 1672 foreign and 22 native sisters, 358 churches and chapels, 363 schools, 28,042 scholars, and 103,880 Catholics. For the African Islands, 188 foreign and 2 native priests, 109 brothers, 195 sisters, 1267 churches and chapels, 182 schools, 32,499 scholars, and 15,300 Europeans and descendants and 223,504 native Catholics. Total for Africa, 2074 foreign and 94 native priests, 1385 brothers, 3819 sisters, 4575 churches and chapels, 4595 schools, 247,589 scholars, and 945,088 Catholics out of an estimated total population of 140,868,051.

As regards British India, the same authority from whom all of these statistics are taken gives the number of foreign priests as 1268, with 1230 native priests, 638 lay brothers, 3592 sisters, 5891 schools and chapels, 3362 schools, 211,035 scholars, and 2,215,632 Catholics. For Asia Minor the figures for 1912 were 527 foreign and 59 native priests, 595 foreign lay brothers, 1187 sisters, 447 churches and chapels, 923 schools, 60,114 scholars, and 138,200 Catholics. For the Philippine Islands the Catholic population is given as 7,455,714, with 963 parish priests, 782 other priests, 29 houses with 559 priests and 195 brothers, 43 houses with 696 sisters, 1339 churches and chapels, 14 seminaries, 32 higher schools, and 10,040 scholars of all kinds. As regards the East Indian islands, in 1912 there were 101 foreign and 2 native priests, 41 brothers, 425 sisters, 112 schools, 9707 scholars, and 37,707 converts, with 180 churches and chapels. In Indo-China the foreign priests numbered 517, with 689 native priests, 149 brothers, 2841 sisters, 4018 churches and chapels, 2986 schools, 73,894 scholars, and 986,597 Catholics. In the Turkish Empire in 1912 the Armenian Catholics numbered 106,000, with 367 bishops and priests; the Syrians 22,200 Catholics and 84 priests, the Syrian Chaldean 64,000 with 251 and the Syrian Maronites 414,600 Catholics with 1517 bishops and priests.

In South America there are nearly 10,000,000 Indians in the various Catholic missions, with some 3,000,000 more unconverted. The separation from Spain, the abolition of slavery in Brazil (1888), the frequent violent expulsion of various religious orders, the movement of immigration from Europe, and the Patagonian missions of the Salesian Fathers since 1875, have been among the principal events that affected the missionary work.

Throughout the islands of Polynesia there were, in 1912, 427 European and 8 native priests, 227 European and 29 native lay brothers, 418 foreign and 120 native sisters, 900 churches and chapels, and a total Catholic population of 193,293.

In 1885 Archbishop Moran, of Sydney, was made a Cardinal and in the same year he held the first council in Australia. There was in Australia in 1912 a total of 828,111 Catholics, 1505 churches and chapels, 1436 various priests, 478 brothers, 5574 sisters, 1181 schools, and 115,178 scholars. In Tasmania and New Zealand there were for the same year 184,876 Catholics, 419 churches and chapels, 388 priests of various kinds, 75 brothers, 164 sisters, 195 schools, and 17,465 scholars.

The most active missionary body of the Roman Catholic church is the Society of Jesus. A quasi-

official statement found in the *Lettres des missionnaires jésuites* (Paris, 1903) gave the number of Jesuit missionaries at that time as 3249. In 1912 they included in their organization 1 cardinal, 11 bishops, 7 apostolic vicars, 7311 priests, 4229 scholars, and 3077 lay brothers. They are active in almost the entire field of missionary work. They are no longer officially sanctioned in France since the separation of church and state, Dec. 9, 1905.

4. *Mission Work in the United States.*—Home-missionary activity in the United States aims chiefly at supplying the spiritual needs of the Indians and negroes. These missions are almost exclusively in the hands of religious orders. In 1885 a special commission was organized to collect and distribute funds for the maintenance of missionaries and schools in the various reservations. Statistics of 1912 claim 64,741 Catholic Indians, with 306 churches, 163 priests, 101 schools, and 7357 scholars; 103,436 Catholic negroes, with 109 churches, 162 priests, 173 schools, and 14,181 scholars.

Another phase of missionary endeavor in the United States is that of missions to non-Catholics inaugurated by the Paulist Fathers in 1893. It consists in explaining by public conference Catholic belief and practice to those non-Catholics who may desire to be enlightened thereon. The idea was soon taken up in various localities, many bishops setting apart a few preachers to carry on this work in their respective dioceses. The movement soon led to the formation of a legal corporation known as the Catholic Missionary Union, and in 1903 to the erection of the Apostolic Mission House in Washington, D. C. This institution is one of the group of those connected with the Catholic University, and its aim is to train young clergymen in missionary methods with a special view to this diocesan work.

Bibliography. For the Propaganda: O. Meyer (Protestant), *Die Propaganda* (Göttingen, 1852); George Phillips, *Kirchenrecht*, vol. vi (Regensburg, 1864); Humphrey, *Urbs et Orbis, or the Pope as Bishop and as Pontiff* (London, 1899). For general statistics: Reliable ecclesiastical geographies, with administrative divisions, subdivisions, maps, and summaries of statistics, are those of O. Werner, *Atlas des missions catholiques* (Freiburg, 1886); id., *Katholischer Kirchenatlas* (ib., 1888); id., *Orbis Terrarum Catholicus, etc.* (ib., 1890). The most recent and valuable of all, with English, French, German, and Italian texts, is K. Streit, *Atlas Hierarchicus* (Paderborn, 1913). In the work of L. E. Louvet, *Les Missions catholiques au XIXème siècle* (Paris, 1898), are to be found an outline history and statistics of all Catholic missions during the last century. Marshall, *Catholic Missions* (London, 1862), is polemical in character; *Die katholische Kirche* (Leo-Gesellschaft, Vienna, 1898 et seq.) is a work in several volumes exhibiting a general view of the entire Roman Catholic church. Consult also: Oudin, *Un siècle* (1800-1900) (Paris, 1901); S. J. Neher, *Der Missionsverein, oder das Werk der Glaubensverbreitung, etc.* (Freiburg, 1894); Goyau, *Le Vatican* (Paris, 1898); *L'Annuaire pontifical catholique* (ib., annually). Catholic directories and almanacs: England, Scotland, and Ireland have each a Catholic directory or register. For the United States there are *Hoffman's Catholic Directory* (Milwaukee) and *Sadler's Catholic Directory* (New York). The ecclesiastical statistics of

France are found in the annual compilation, *Le clergé français* (Paris); those of Canada in *Le Canada ecclésiastique* (Montreal); for Italy one may consult the *Annuario ecclesiastico* (Rome) and the *Guida ecclesiastica d'Italia* (Savona, 1885); for Spain, the *Guida del estado ecclésiastico*, published from time to time at Madrid.

French missions: The best account of the missions of the Roman Catholic church in France is that of Kannengiesser, *Les missions catholiques: France et Allemagne* (Paris, 1900). For a summary of this work, consult Shahan, "The Catholic Missionaries in France and Germany," in the *Catholic World* (New York, 1900); also Lacroix, *Dictionnaire des missions catholiques* (Paris, 1863). J. B. Piolet, *Les missions catholiques françaises au XIXème siècle* (6 vols., Paris, 1900-03), may also be consulted.

German missions: The work of Kannengiesser gives the statistics of German Roman Catholic missions to 1900. Consult also the *Schematismus der römisch-katholischen Kirche des deutschen Reiches* (Freiburg, annually); and for Austria, *Schematismus des gesammten katholischen Reiches Oesterreich-Ungarns* (Vienna); *Kloster-Schematismus für das deutsche Reich* (3d ed., Paderborn, 1899); Zak, *Oesterreichisches Klosterbuch: Statistik der Orden und Kongregationen der Kathol. Kirche in Oesterreich* (Vienna, 1911); Goyau, *L'Allemagne religieuse* (Paris, 1899); A. Huonder, *Deutsche Jesuitenmissionäre des 17. und 18. Jahrhunderts* (Freiburg, 1899); Kannengiesser, *Les catholiques allemands* (Paris, 1893); Max Heimbucher, *Die Orden und Kongregationen der katholischen Kirche* (2d ed., Paderborn, 1907), and H. A. Krose, *Kirchliches Handbuch für das katholische Deutschland* (Freiburg, 1907 et seq.).

Mission periodicals: The Congregation of the Propaganda publishes from time to time (1886-1914) the *Missiones Catholicae*, containing official statistics of its missions. The Work of the Propaganda of the Faith publishes frequently each year the *Annales de la propagation de la foi* (Paris), and a similar *Annales* is published by the Work of the Holy Childhood (Lyon). For the African missions there are the *Bulletin des missions d'Afrique* and the *Société anticléricaliste*, both published annually at Paris. The details of Roman Catholic education in the Orient are found in the periodical *Œuvres des Ecoles de l'Orient* (Paris, annually). An illustrated monthly entitled *Catholic Missions* appears in English, French, and German, and offers popular information concerning all Catholic missionary work (London). Other important periodicals are: *Annalen der Gesellschaft der Verbreitung des Glaubens* (Einsiedeln, 1832 et seq.); *Jahrbücher der Verbreitung des Glaubens* (Cologne, 1829 et seq.); *Das heilige Land* (ib., 1857 et seq.); *Die katholischen Missionen* (Freiburg, 1874 et seq.).

United States missions: The statistics of the native Roman Catholic missions are found since 1864 in the *Reports of the Commission for Negro and Indian Missions* (Baltimore, annually). Previous to that year the voluminous works of J. D. G. Shea, *History of the Catholic Church in the United States* (4 vols., New York, 1886-92); id., *Catholic Church in Colonial Days, 1521-1763* (Boston, 1887), may be consulted; also id., *History of the Catholic Missions Among the Indian Tribes [1592-1854]* (New York, 1876), and id., *Discovery and Exploration of the Mississippi Valley* (2d ed., Albany, 1903); as

well as the numerous writings of Father de Smedt, a Belgian missionary among the Indian tribes of the Far West. Their bibliography is to be found in J. D. G. Shea, *Western Missions and Missionaries* (New York, 1878); also, T. O'Gorman, *History of the Roman Catholic Church in America* (ib., 1895); Francis Parkman, *The Jesuits in North America* (ib., 1902); De Courcy, *History of the Catholic Church in the United States* (ib., 1904); and Zephyrin Engelhardt, *Missions and Missionaries of California* (3 vols., San Francisco, 1908-13).

For the Philippines, see Fidel de Blas de la Asunción, *Labor evangélica de los padres recolectos en las Islas Filipinas* (2d ed., Saragossa, 1910).

For the Near and Farther Orient: Charles Dallet, *Histoire de l'église de Corée* (Paris, 1874); De l'Huys, "Le Christianisme au Tonkin," in *Le Correspondant* (ib., 1889); Adrien Launay, *Atlas des missions de la Société des Missions Etrangères* (ib., 1890); id., *Nos missions: album des missions catholiques* (Lyons, 1900); Léon Joly, "Missions catholiques de l'Indo-Chine, de la Chine, et de la Corée," in his *Le Christianisme et l'extrême Orient*, vol. i (Paris, 1907); Fernández, *Missiones Ordinis Fratrum Minorum in Sinis et in Japonia an. 1908-09* (Quaracchi, 1910). For India: Father Leo, *The Capuchin Mission in the Punjab* (Mangalore, 1910); the *Catholic Directory of India for 1913* (Madras, 1913). On the Catholic missions in Australia: Lemire, *Le Catholicisme en Australie* (Paris, 1900); also the *Australasian Catholic Directory for 1912* (Sydney, 1912). For the religious disturbances in China at the close of the last century, consult articles in *Le Correspondent* (Paris, July 25 and Aug. 10, 1900). Much valuable information of this period is also found in Cordier, *Histoire des relations de la Chine avec les puissances occidentales*, vol. iii (Paris, 1902). For details of earlier Catholic missions in China consult the Abbé Huc, *Le Christianisme en Chine, en Tartarie et en Thibet* (Paris, 1859). Recent statistics are found in Calendrier, *Annuaire pour 1912* (Shanghai, 1912). For other books on

China, see *Aperçu historique sur la Chine* (Rome, 1873); Hubner, *Ein Spaziergang um die Welt* (Leipzig, 1875); J. E. Reiffert, *Zehn Jahre in China* (Paderborn, 1896); Bertram Wolferstan, *The Catholic Church in China* (St. Louis, 1910). For other parts of the Orient: Müllinen, *Die lateinische Kirche im türkischen Reiche* (2d ed., Berlin, 1903); Silbernagl, *Verfassung und gegenwärtigen Bestand sämtlicher Kirchen des Orients* (2d ed., Regensburg, 1904); Lubeck, *Die christlichen Kirchen des Orients* (Kempten, 1911). See also the periodical *Echos d'Orient* (Paris, 1898 et seq.).

For Africa, besides the periodicals named, see *Geographie de l'Afrique chrétienne* (Paris, 1892), and F. Klein, *Kardinal Lavigerie und sein afrikanisches Werk* (Strassburg, 1893).

MISSISAGA, mis'si-sá'gà or -sá'gà. An Algonquian tribe of North American Indians residing east and south from Lake Ontario, Ontario, Canada. They are closely connected with the Ojibwa, of whom they are an offshoot. The name is said to mean "great mouth," referring to the mouth of the Missisaga River. When first known to the French, early in the seventeenth century, the Missisaga were living upon the lower part of the river which bears their name and upon the adjacent Manitoulin Island. Soon afterward they moved east and south into the country left unoccupied by the dispersion of the Huron and Ottawa and soon spread over the whole peninsula of Lower Ontario. At the close of the Revolution they even had one village on the south side of Lake Erie in what is now Ohio. The land on which the Iroquois are now settled on Grand River, Ontario, was bought from the Missisaga. On account of the former loose distinction between the Missisaga and Ojibwa, it is impossible to give exact figures of population. Those now officially classed as Missisaga number about 750, on small reservations at New Credit, Alnwick, Mud Lake, Rice Lake, and Scugog, Province of Ontario, Canada. They are all members of the Methodist church and support themselves by farming, fishing, trapping, gathering wild rice, basket making, and outside labor.
